

# Dynamics of spatial metastatic systems during adaptive therapy

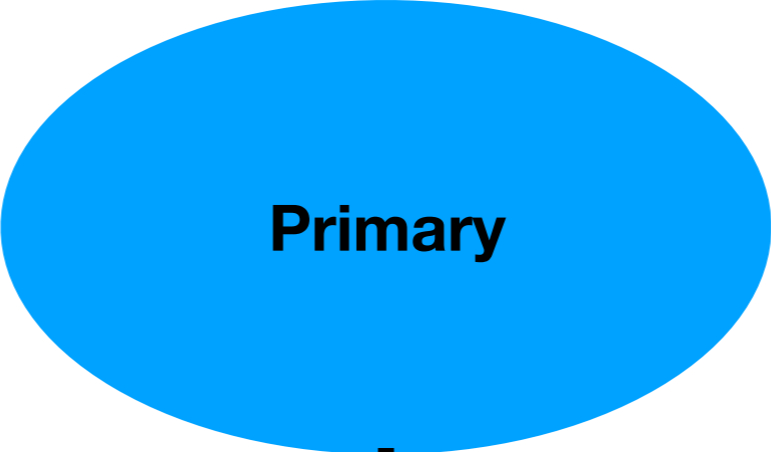

Jill Gallaher  
Moffitt Cancer Center  
CATMO 2020

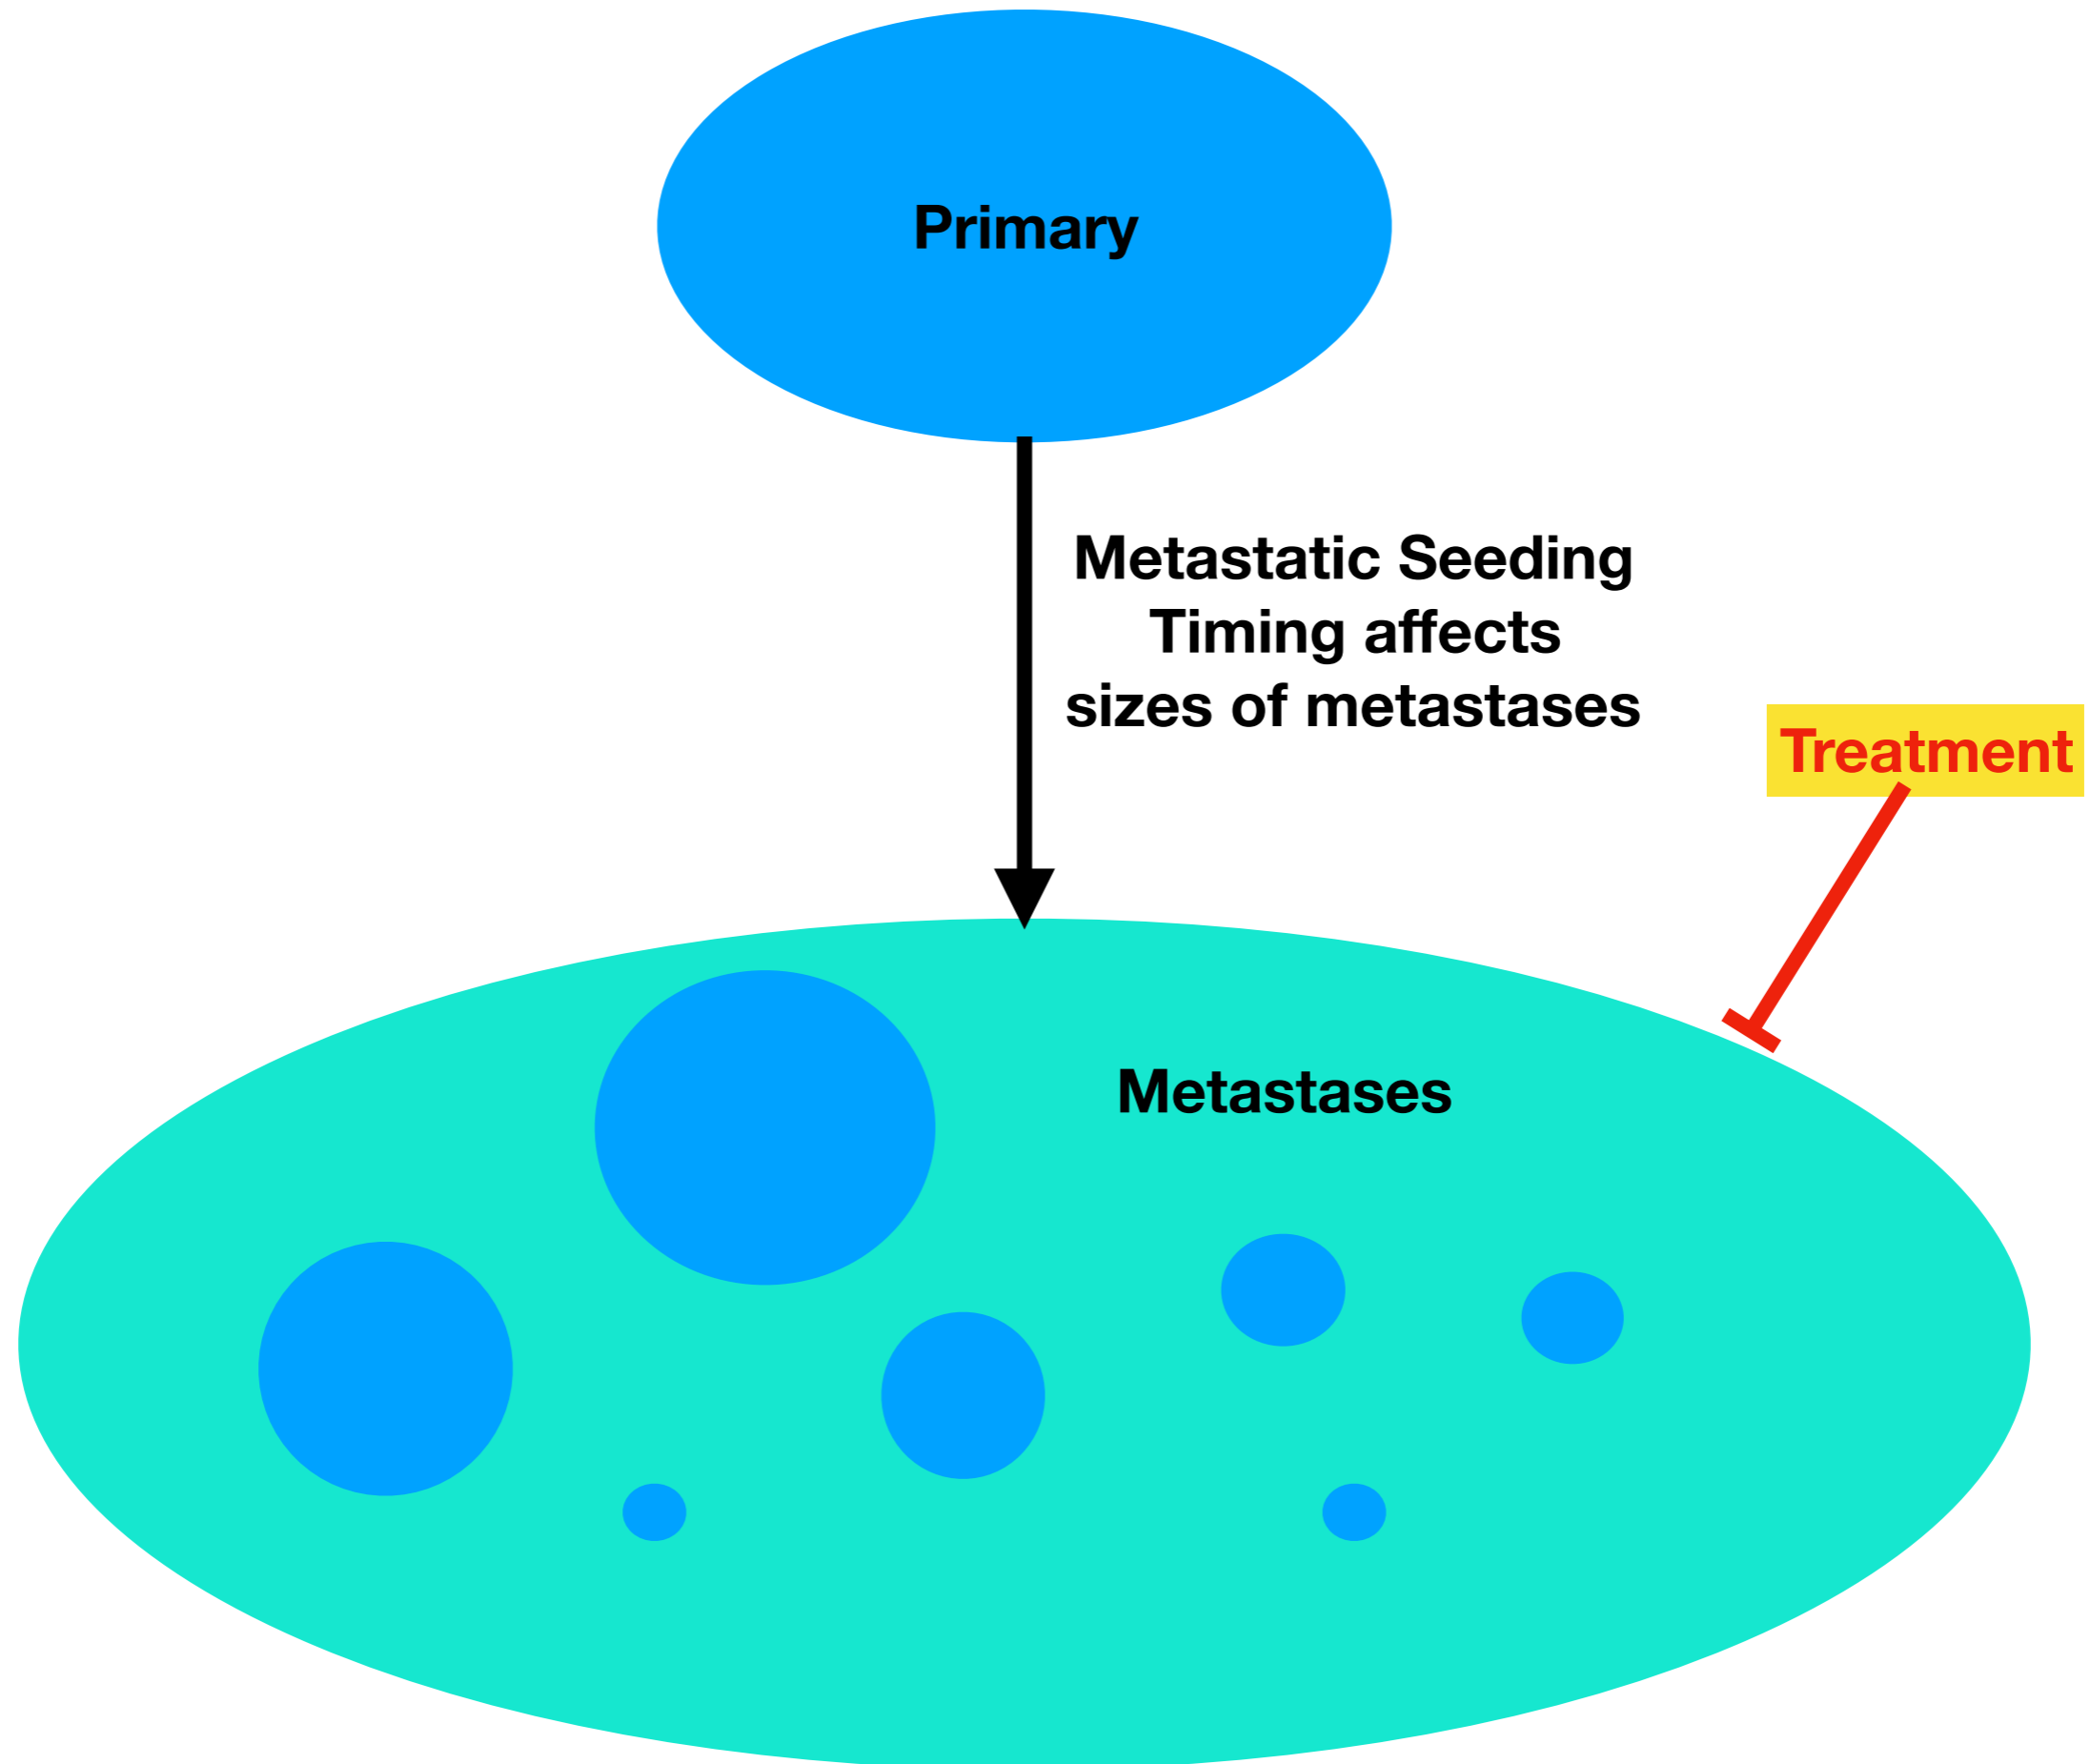

# To kill or control?

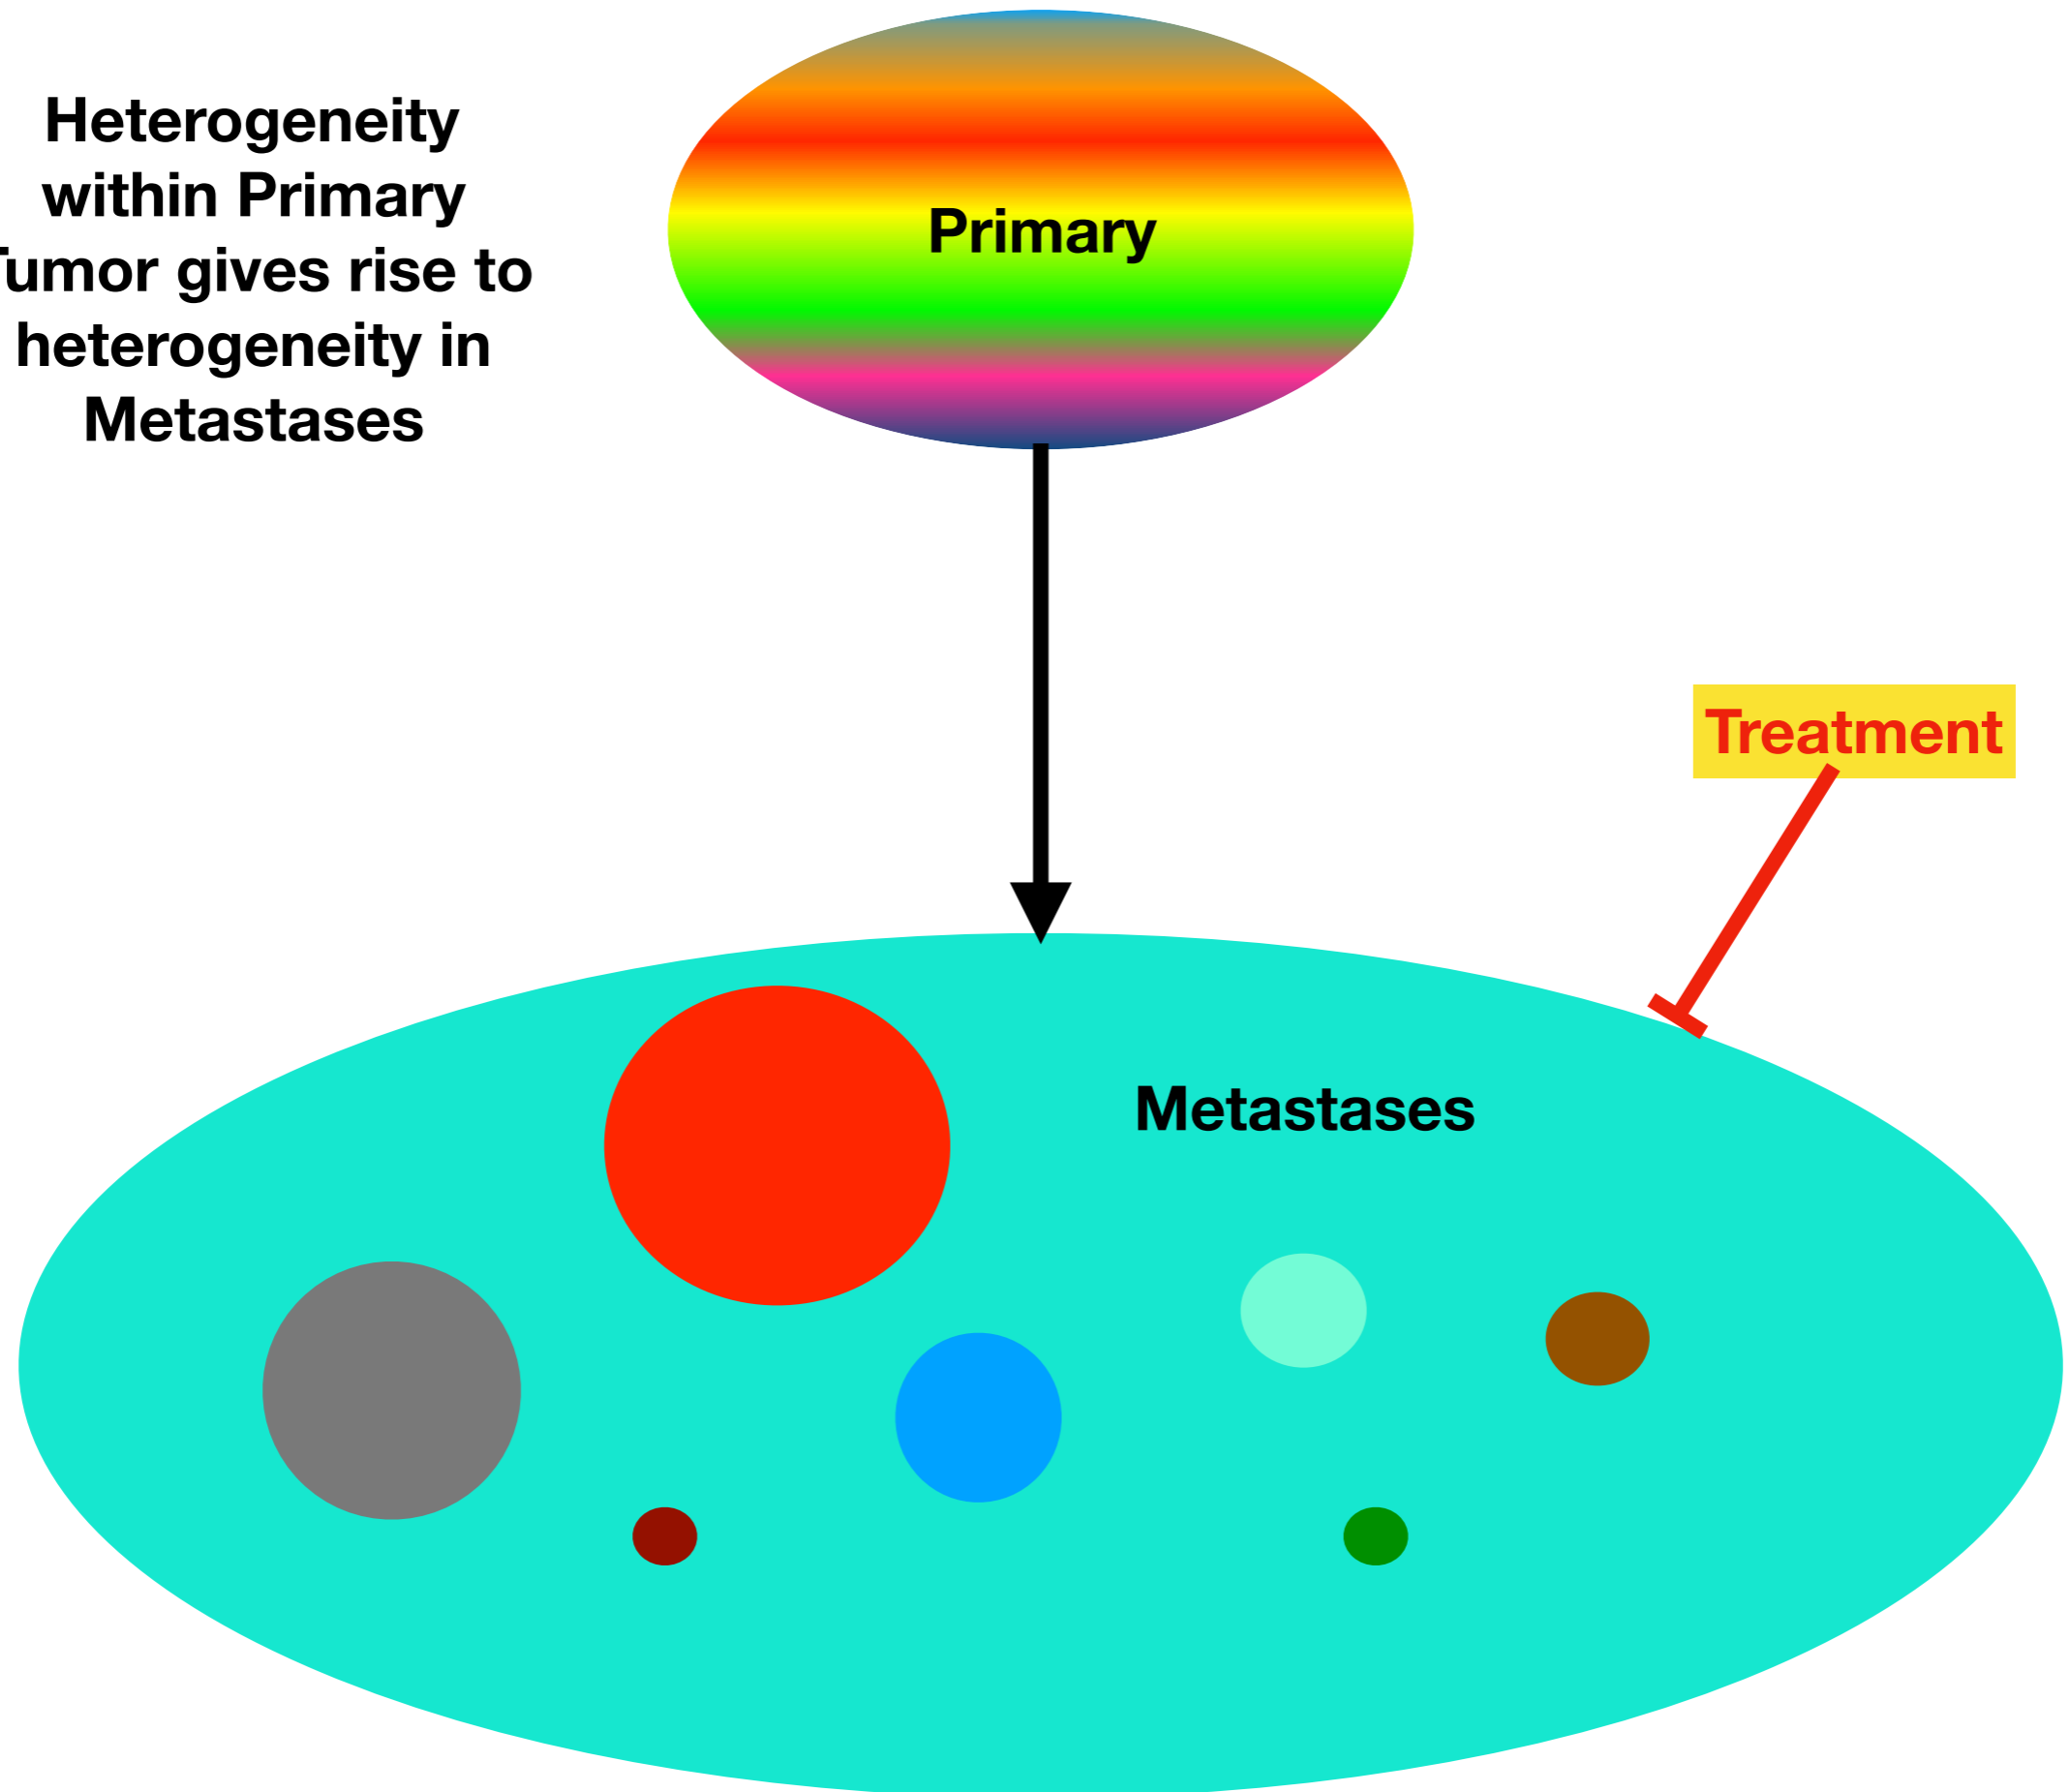

**... BUT adaptive therapy can also be about characterization of the disease state**

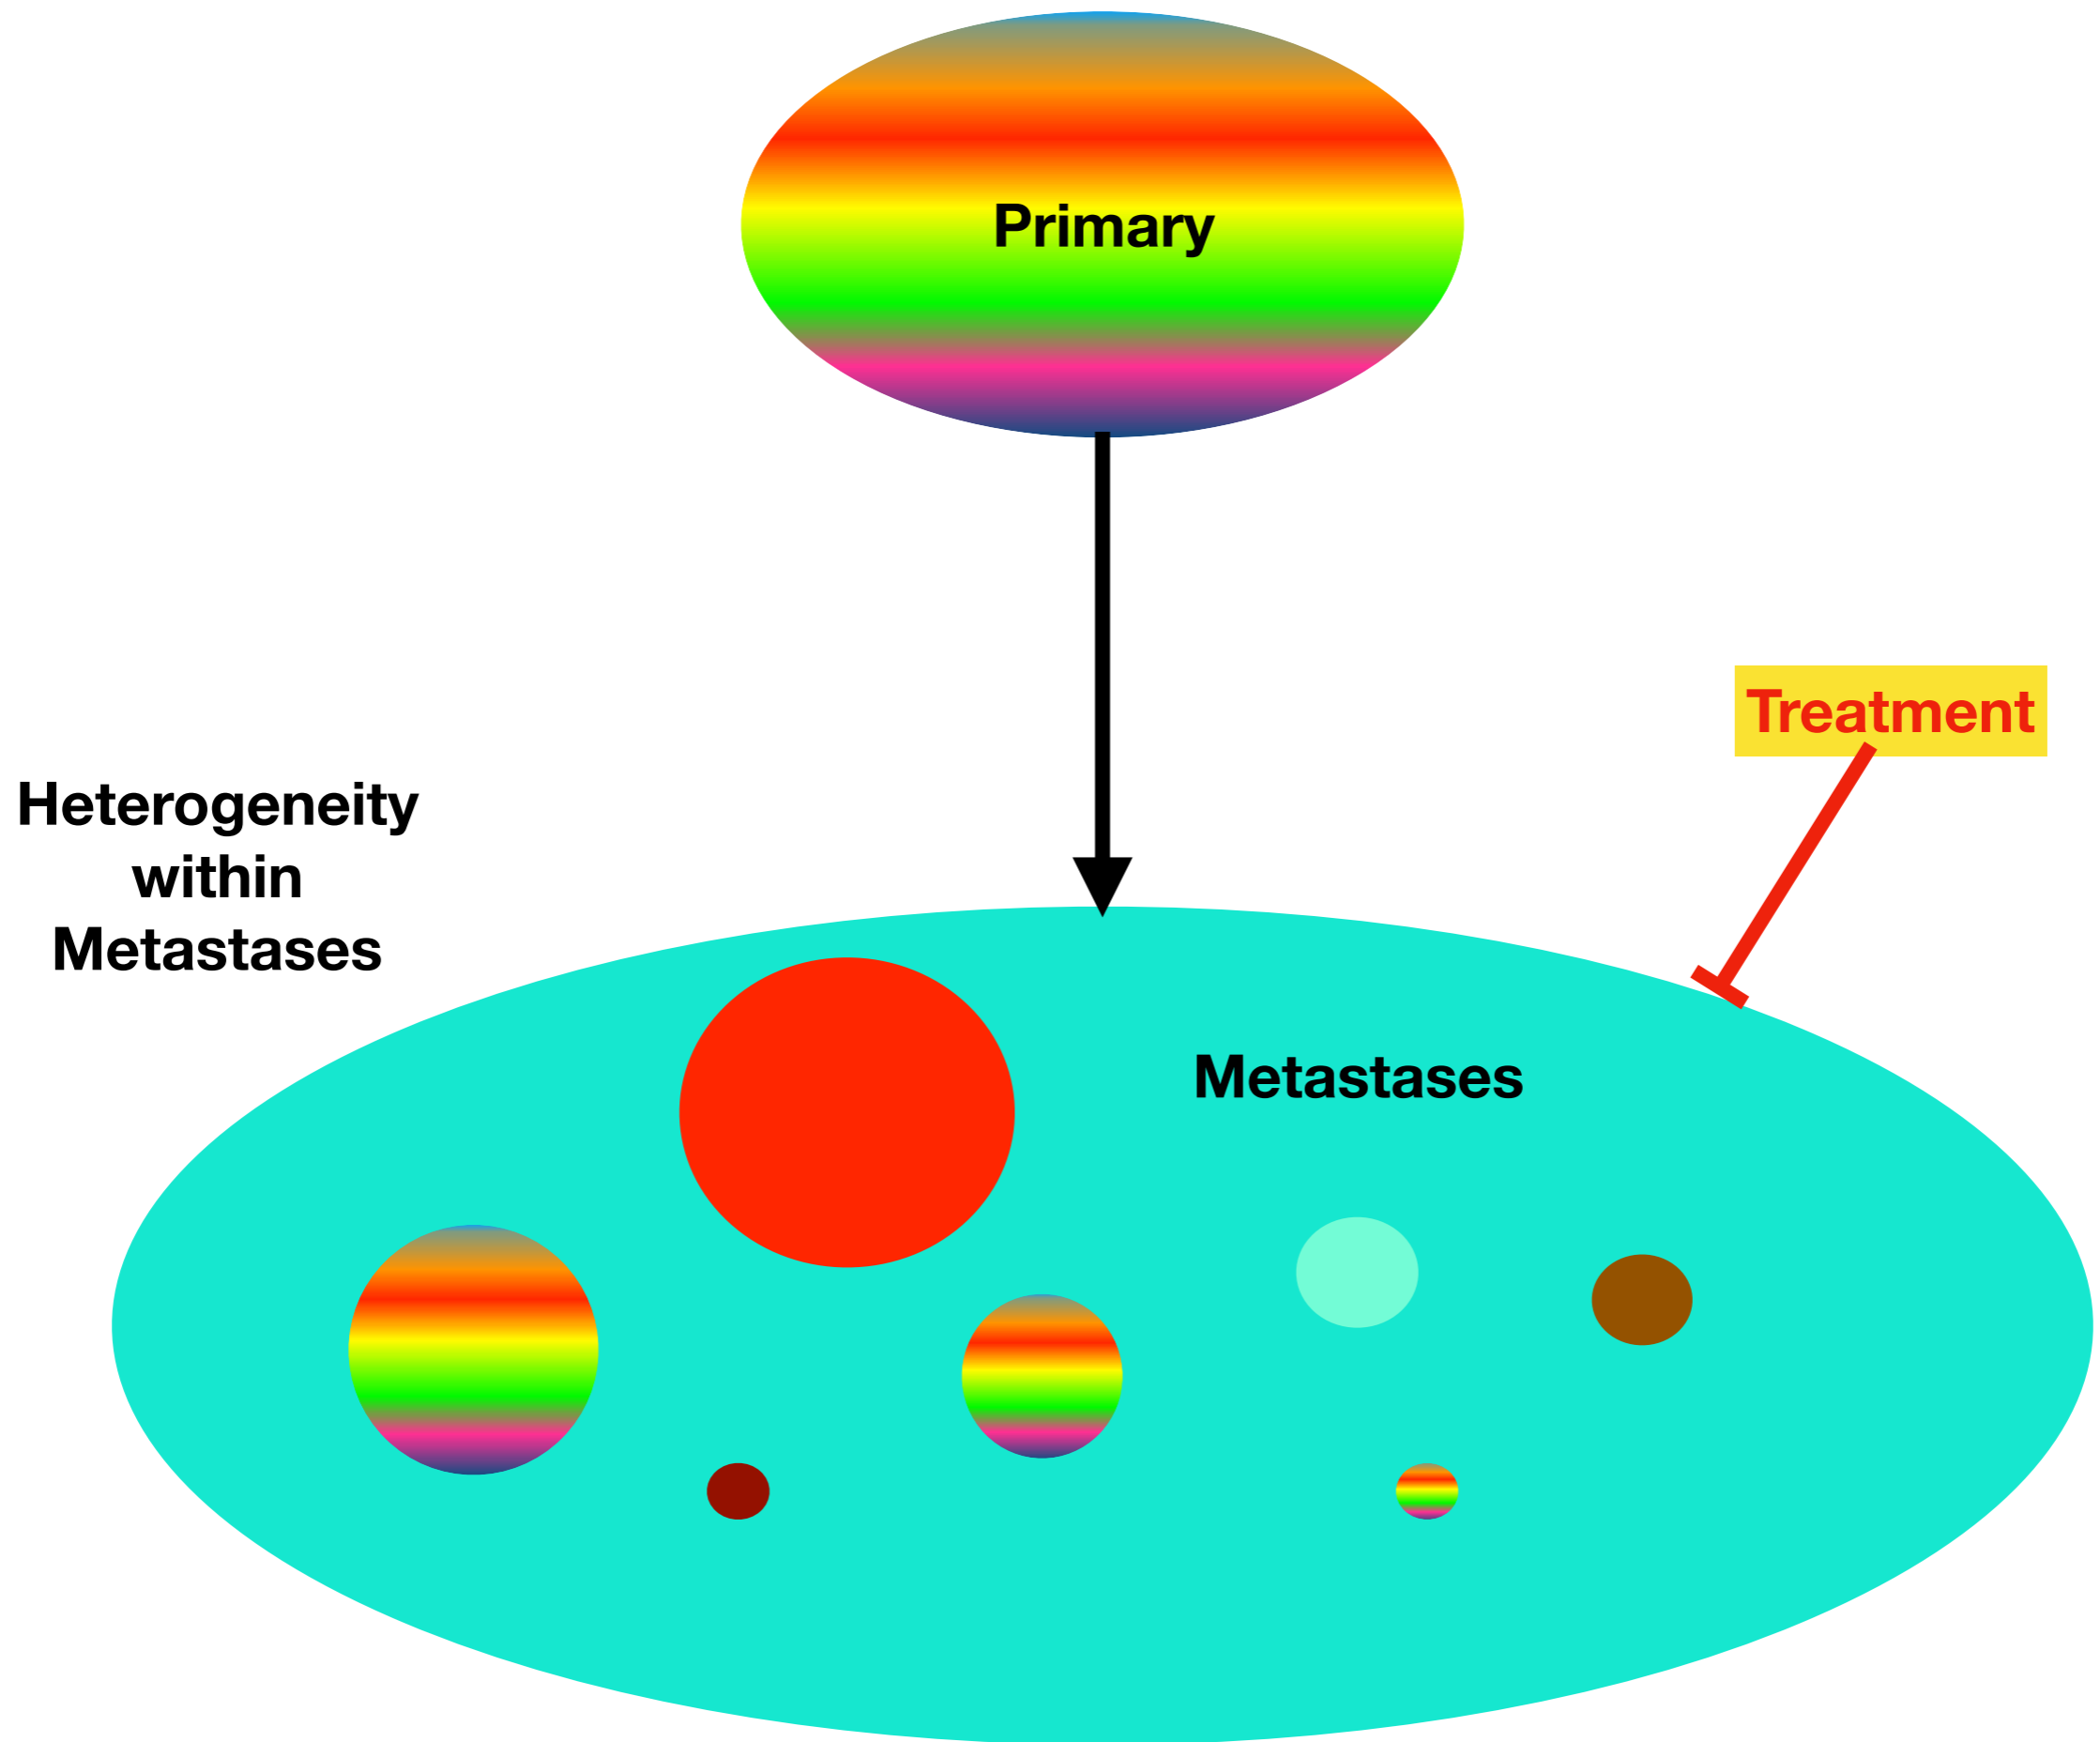

**simple, right?**

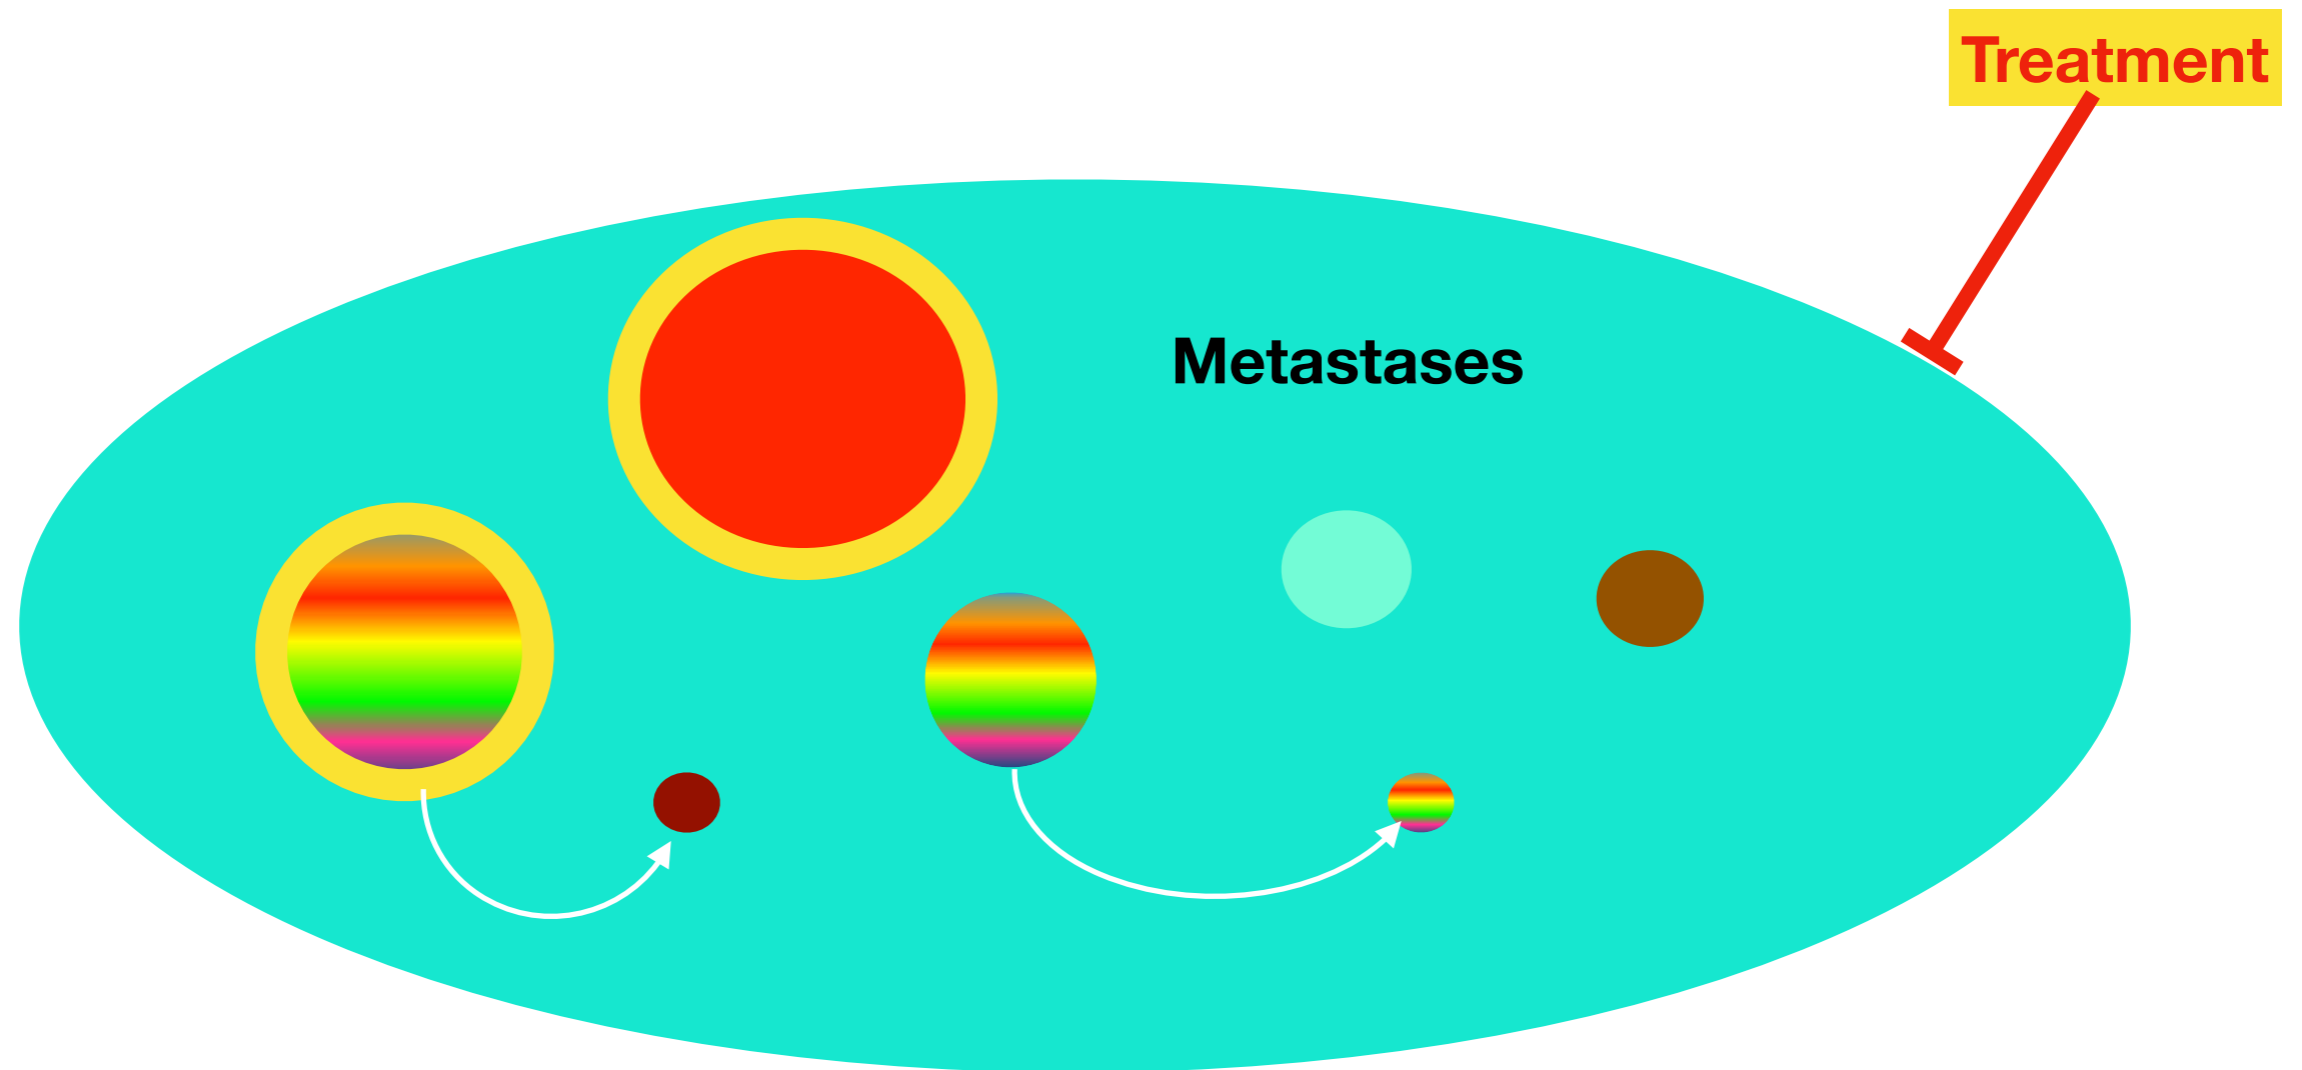

**Heterogeneity  
within Primary  
Tumor gives rise to  
heterogeneity in  
Metastases**

**There could be seeding from  
mets to mets**

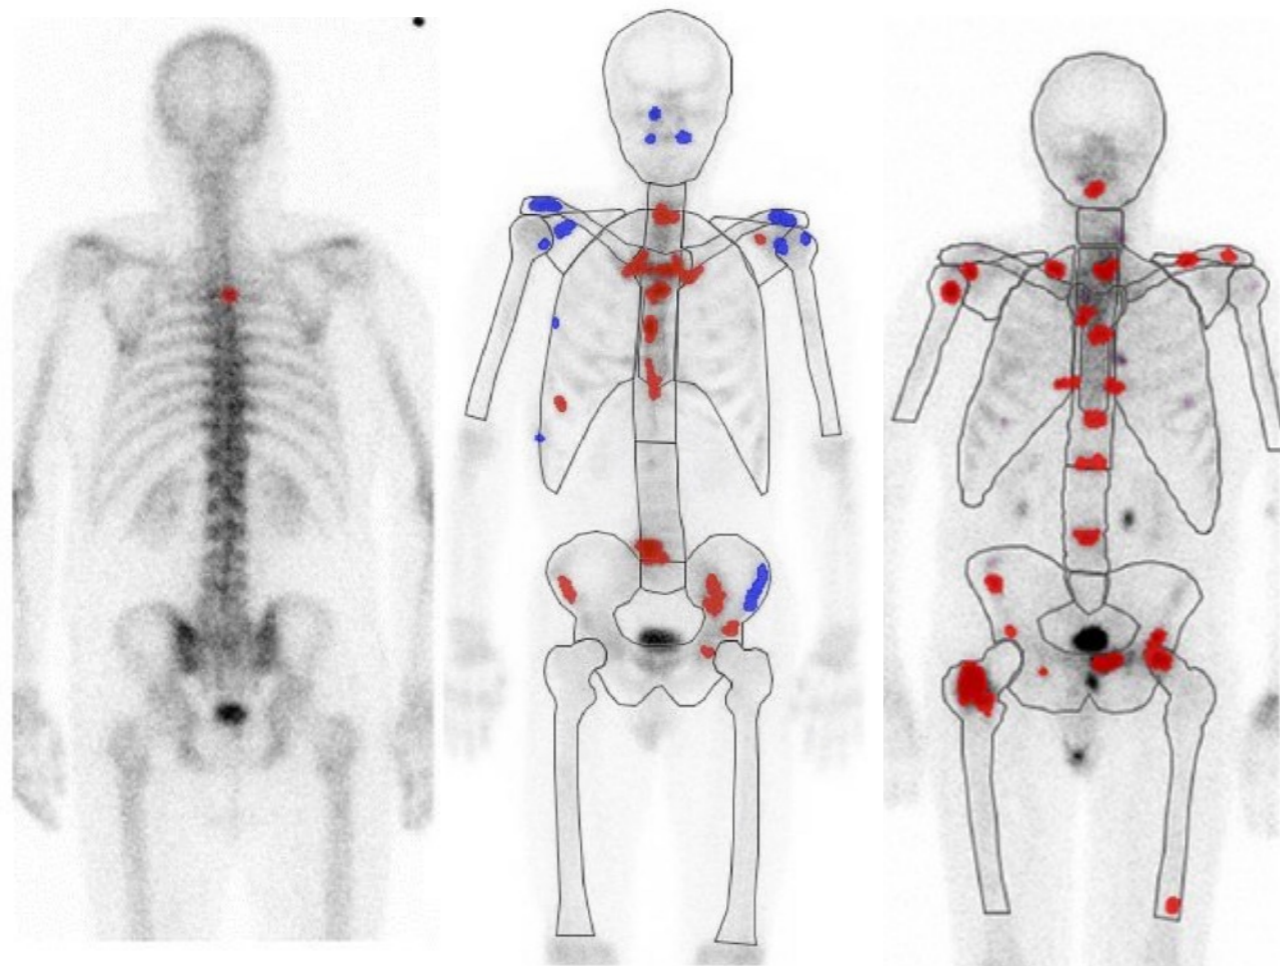

# Metastases are not binary.

“One of the reasons metastasis is so difficult to define is that the same word describes the process and the outcome.”

Do we need to redefine a cancer metastasis and staging definitions?

[Danny R. Welch](#), Ph.D.

[Breast Dis. 2006; 26: 3–12.](#)

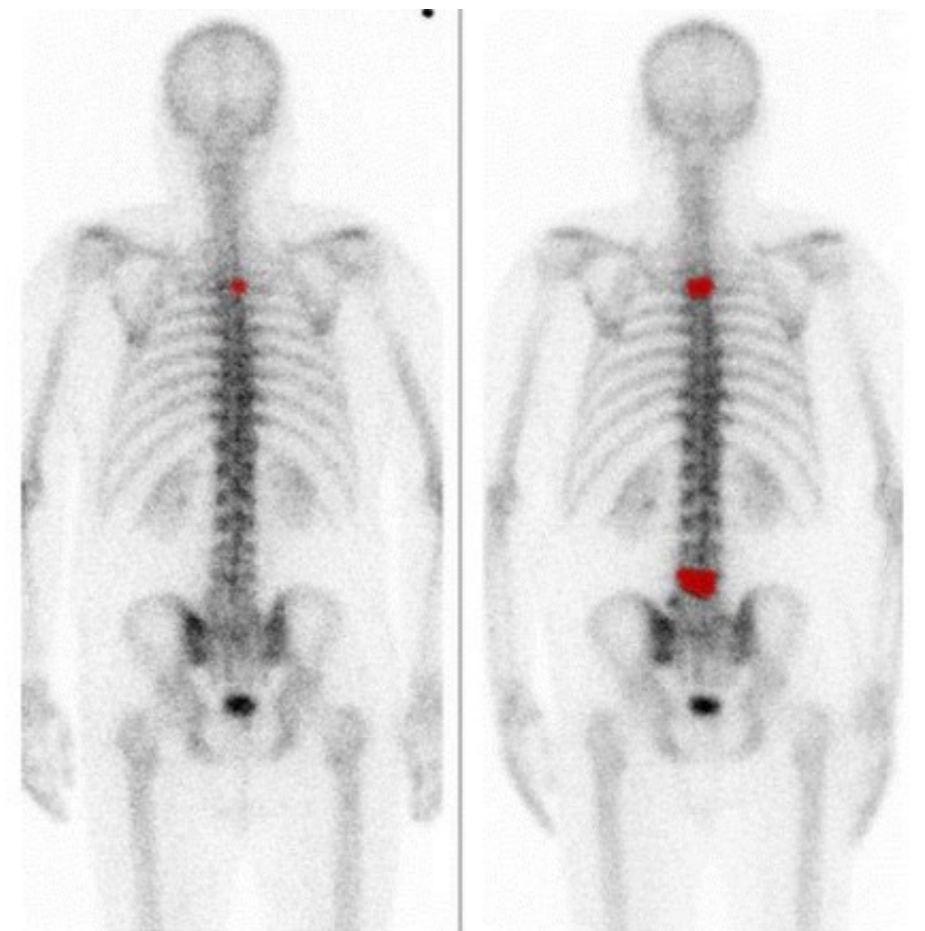

**Different distributions of mets**

“To me, cancer is a verb, not a noun. ‘You’re cancering.’ It’s not something the body gets, it’s something the body does.”  
-David Agus

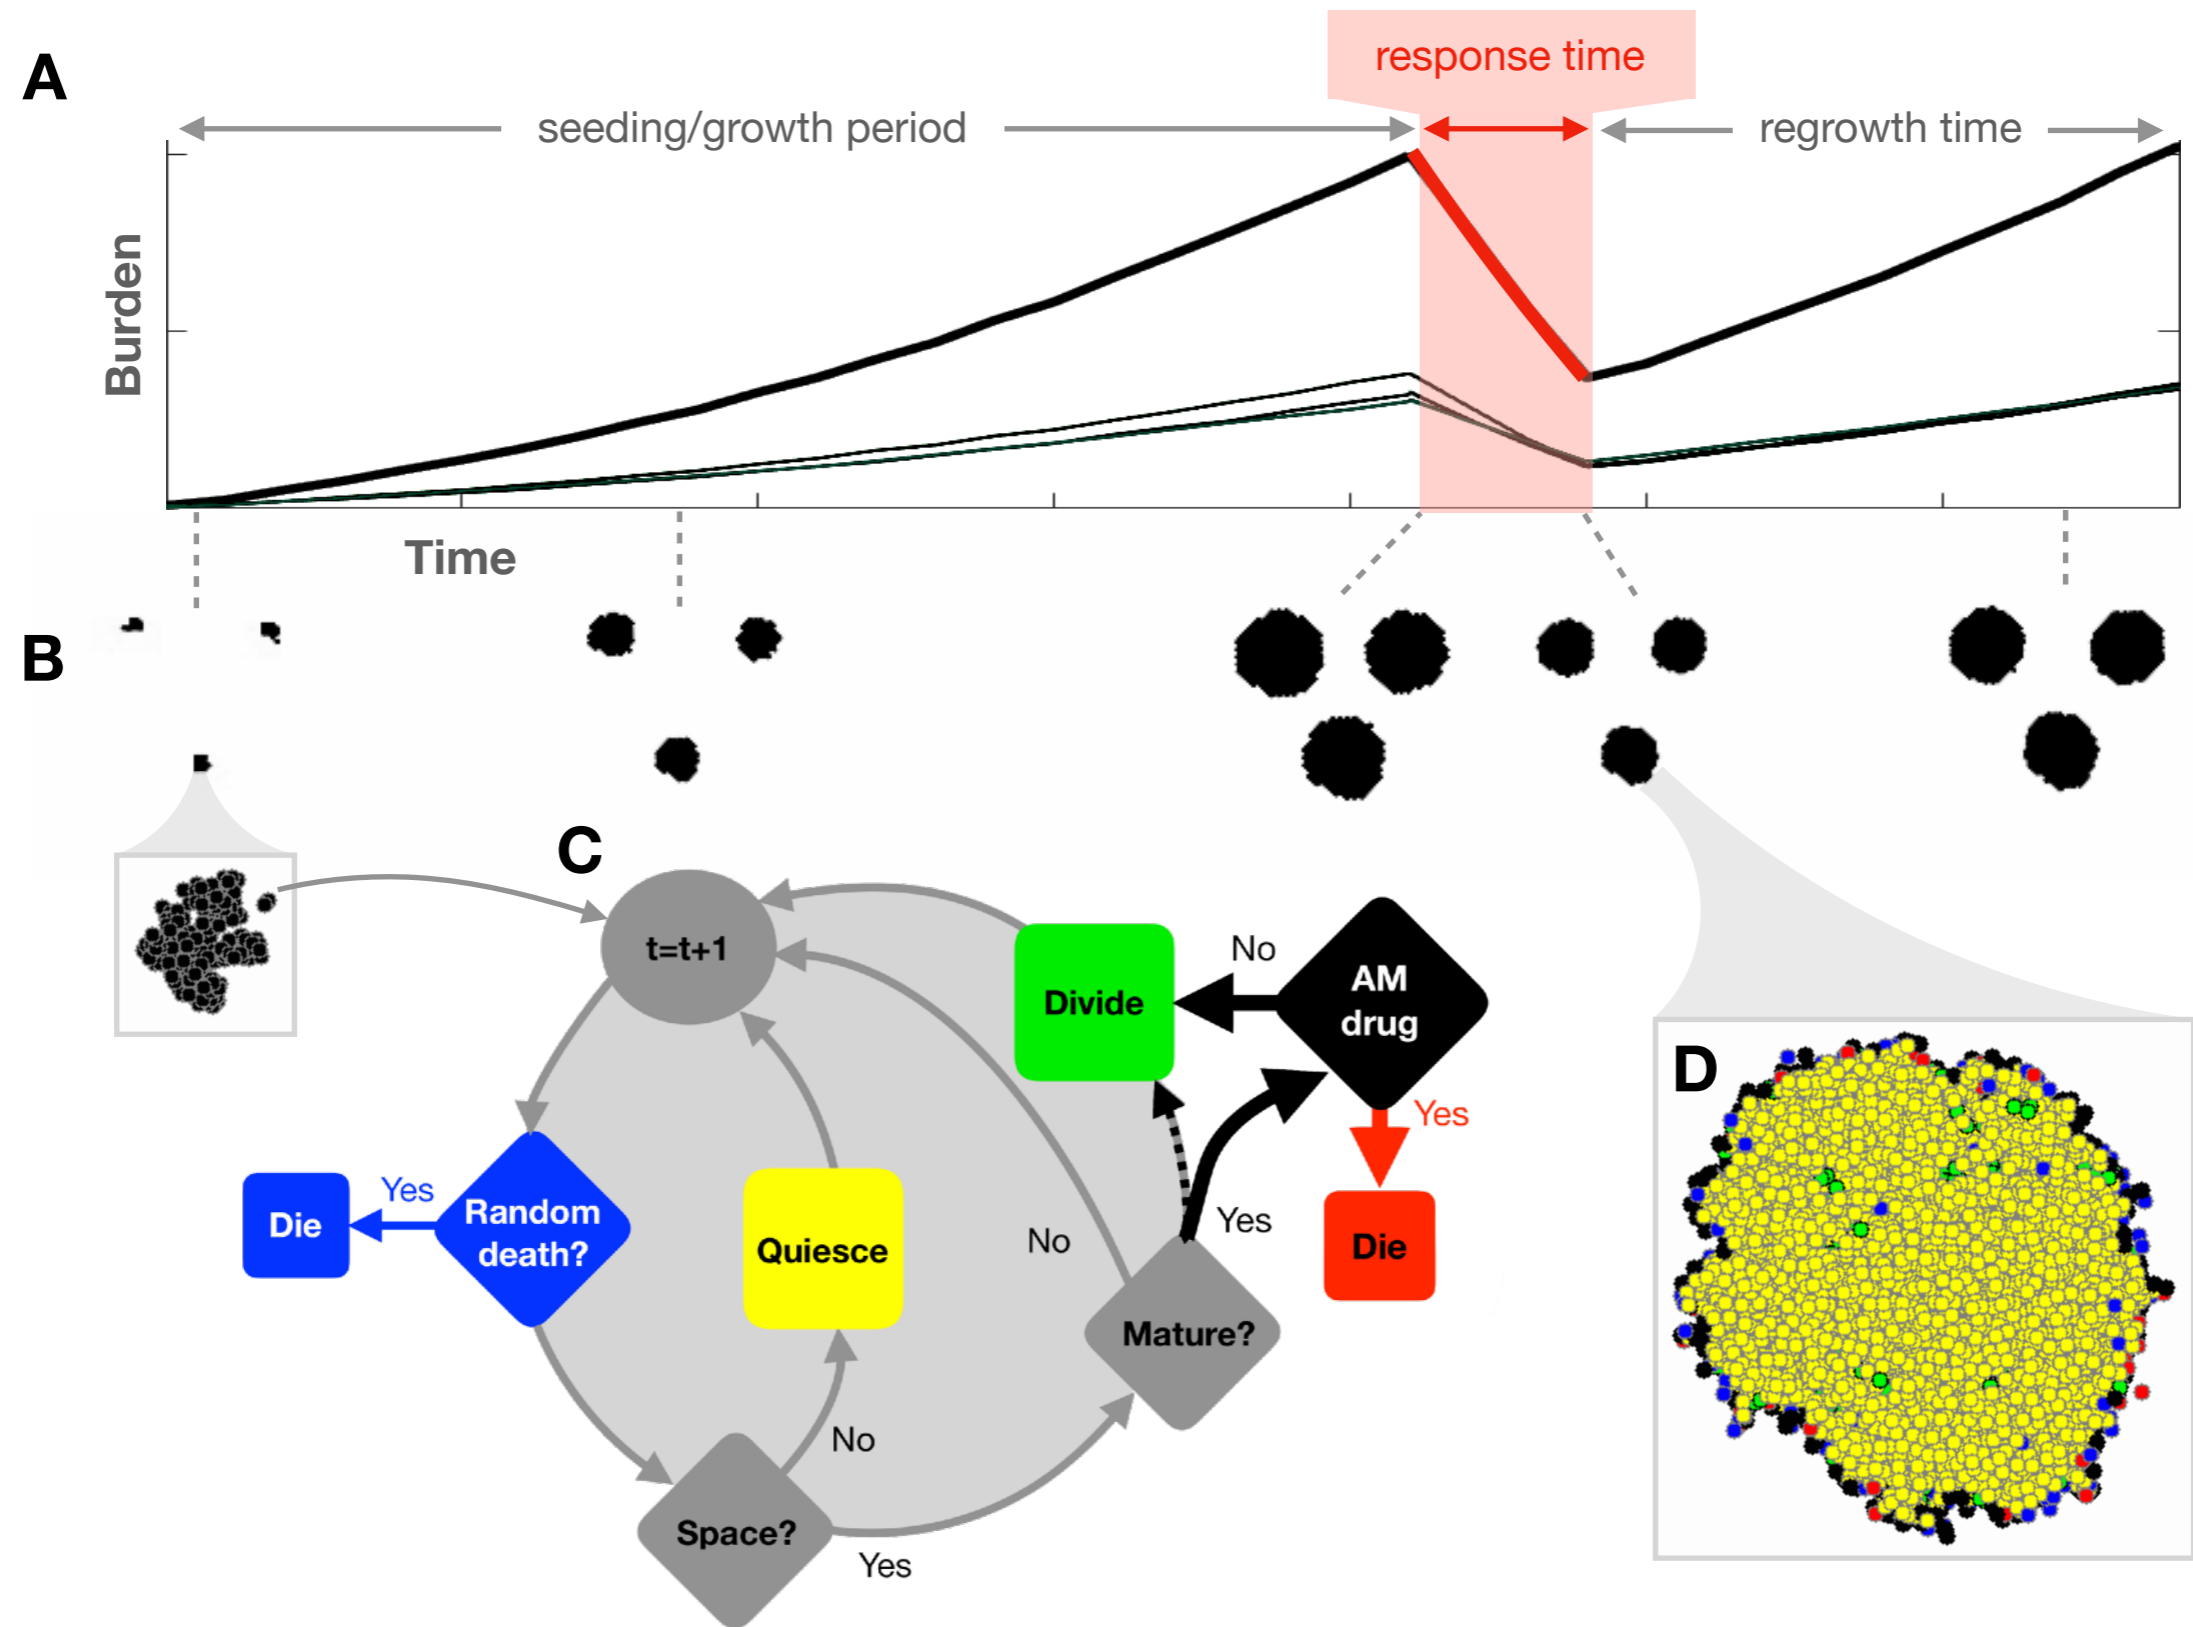

**Pre-Tx**

**Post-Tx**

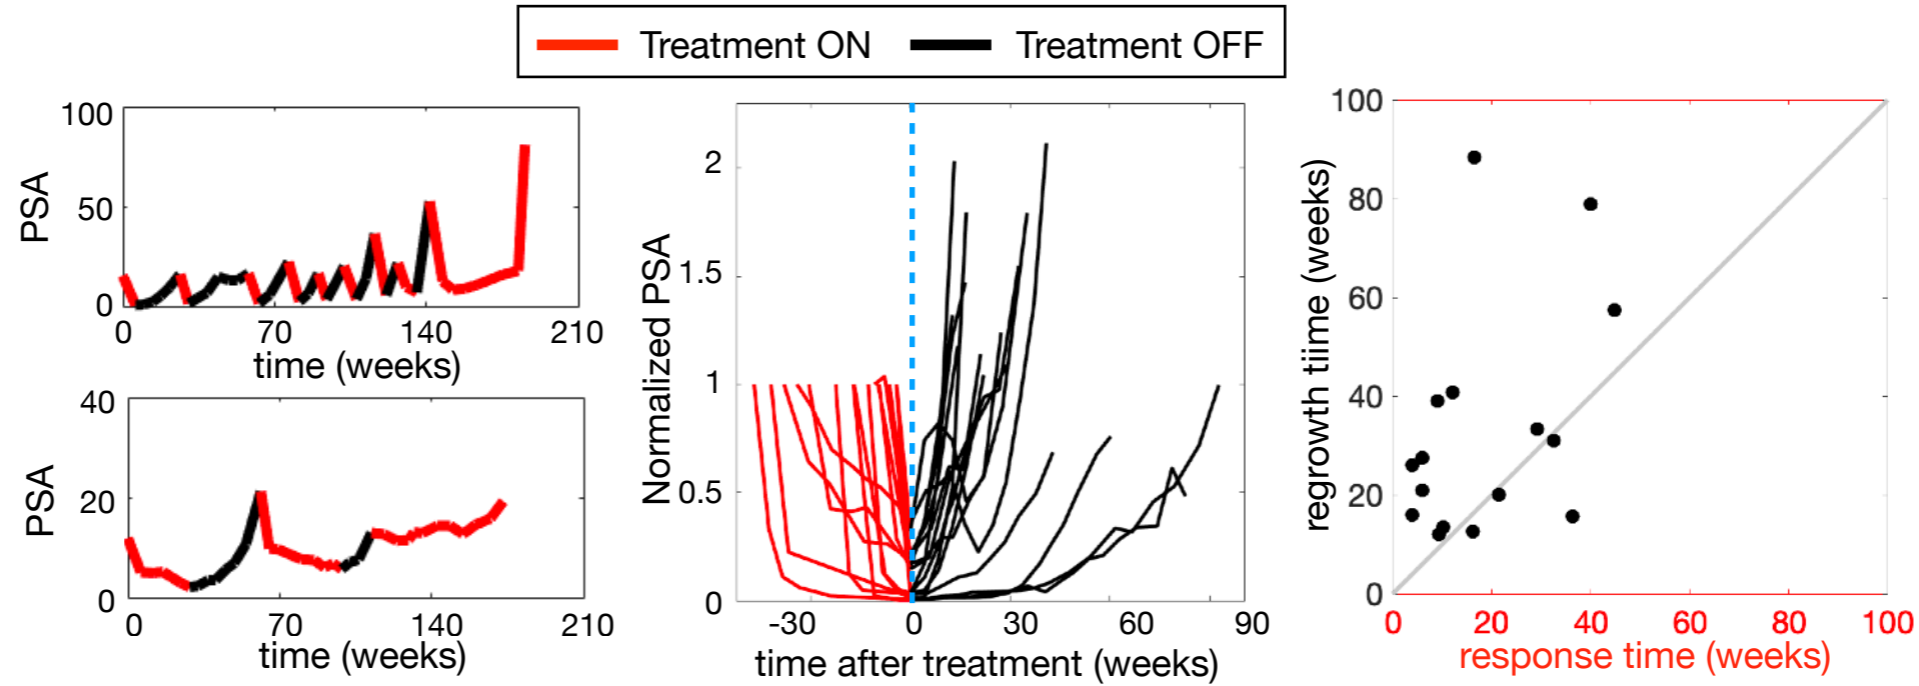

**Change in mets over time**

# Model framework

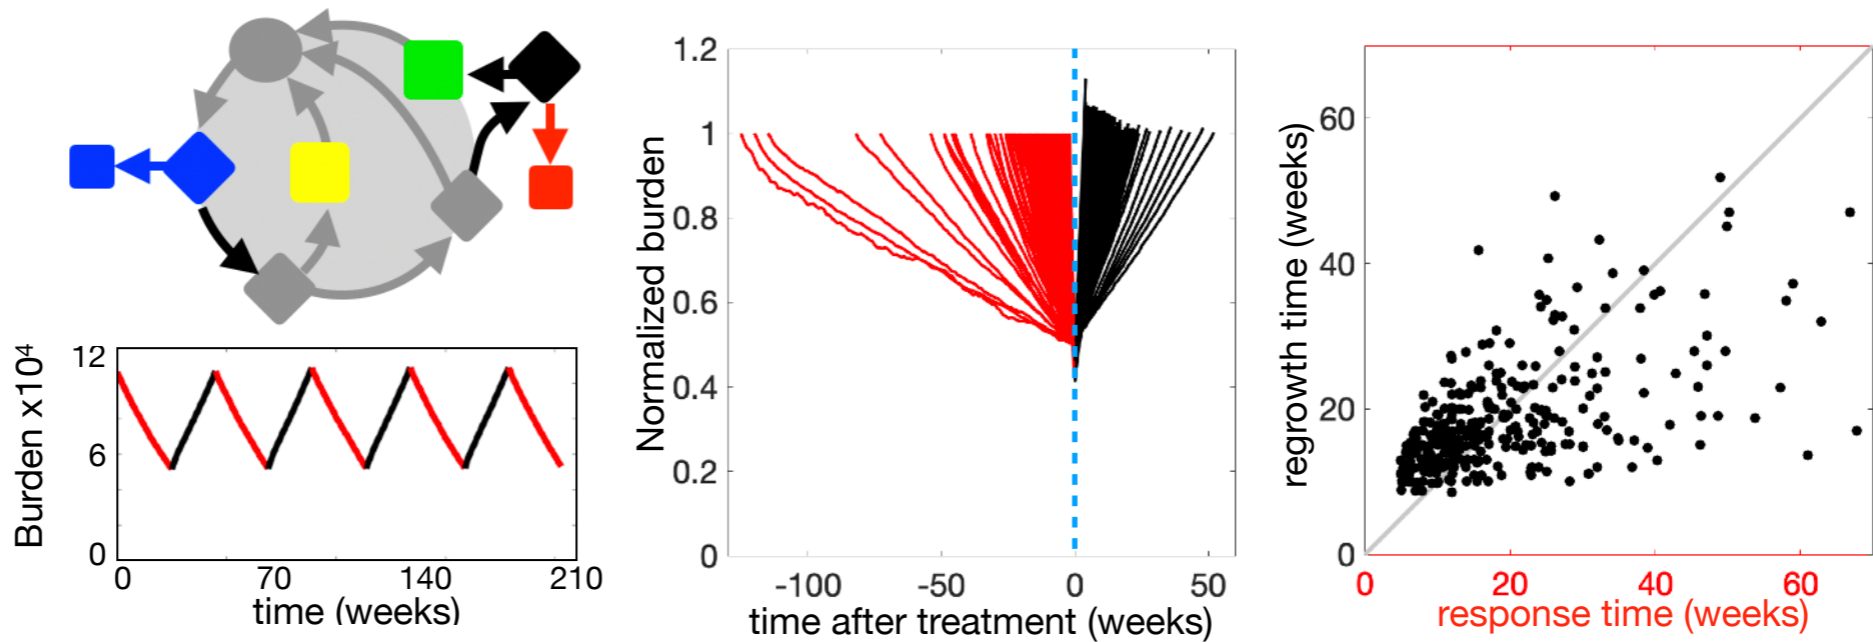

**What affects adaptive therapy cycle dynamics?**

AT  
trial data

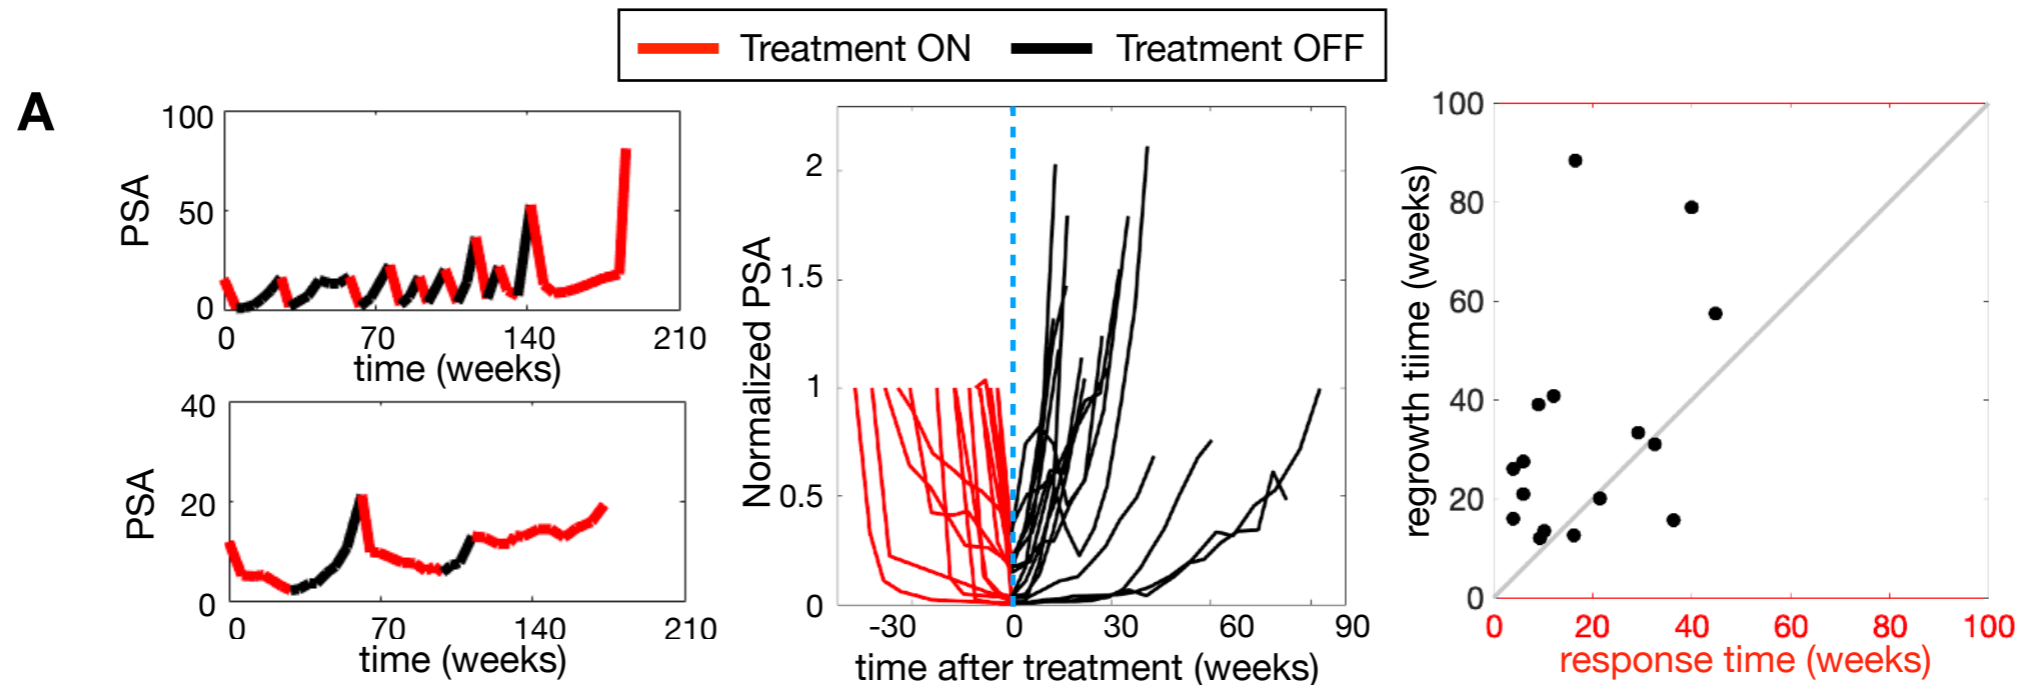

Parameter	Meaning	Value	Units
b	total cell burden	20,000-150,000	cells
m	metastases count	1-10	mets
s	sensitivity	60-100	%
d	cell turnover	0-0.06	day <sup>-1</sup>
$\sigma_{S1}$	Intertumor heterogeneity	0	%
$\sigma_{S2}$	Intratumor heterogeneity	0	%

model:  
cell cycle  
dependent  
drug

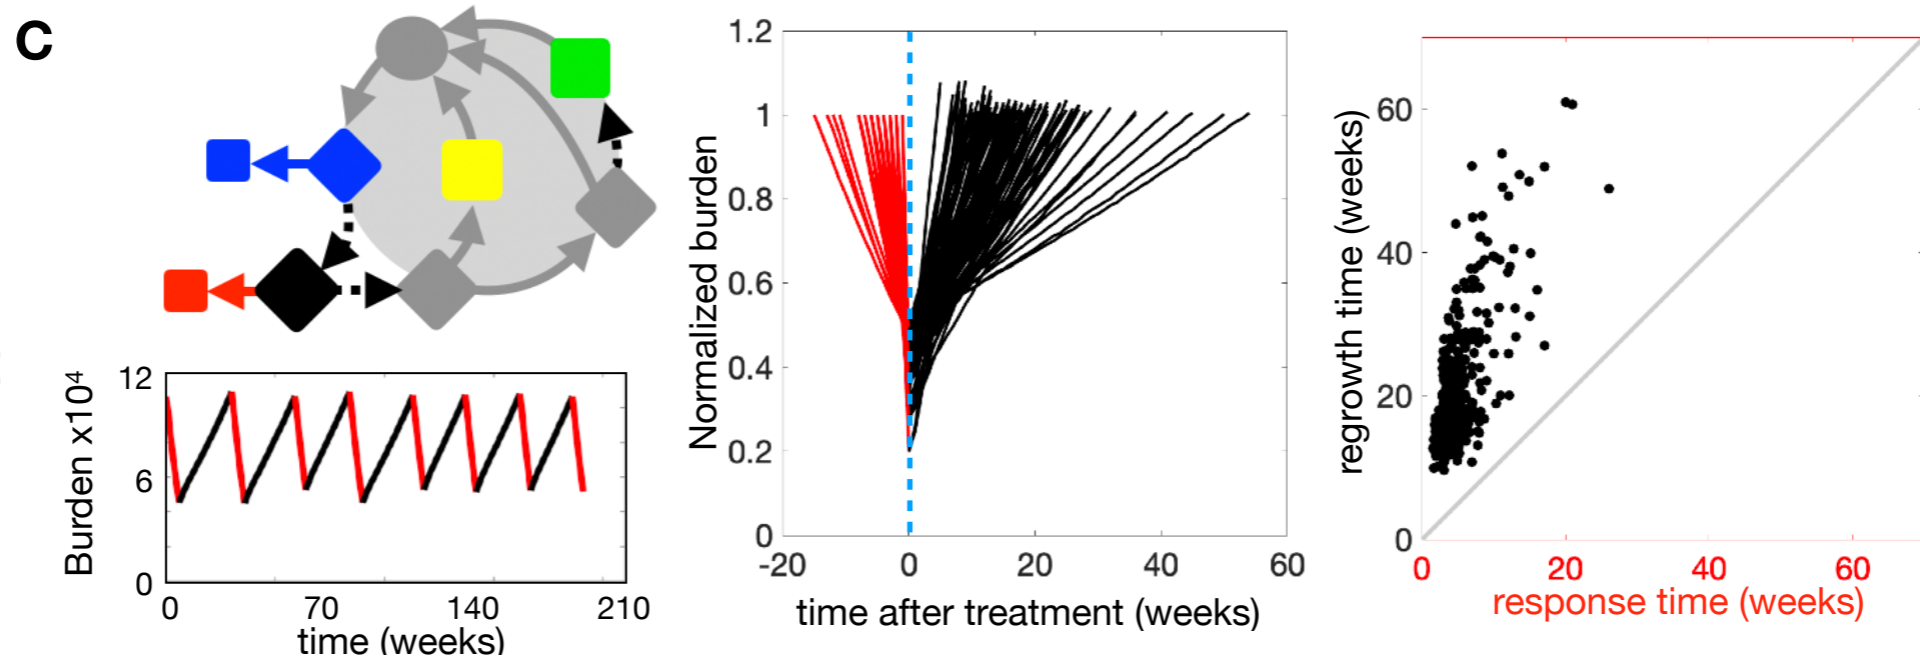

# Cell cycle independent drug shifts toward quicker response times and longer regrowth times

**AT  
trial data**

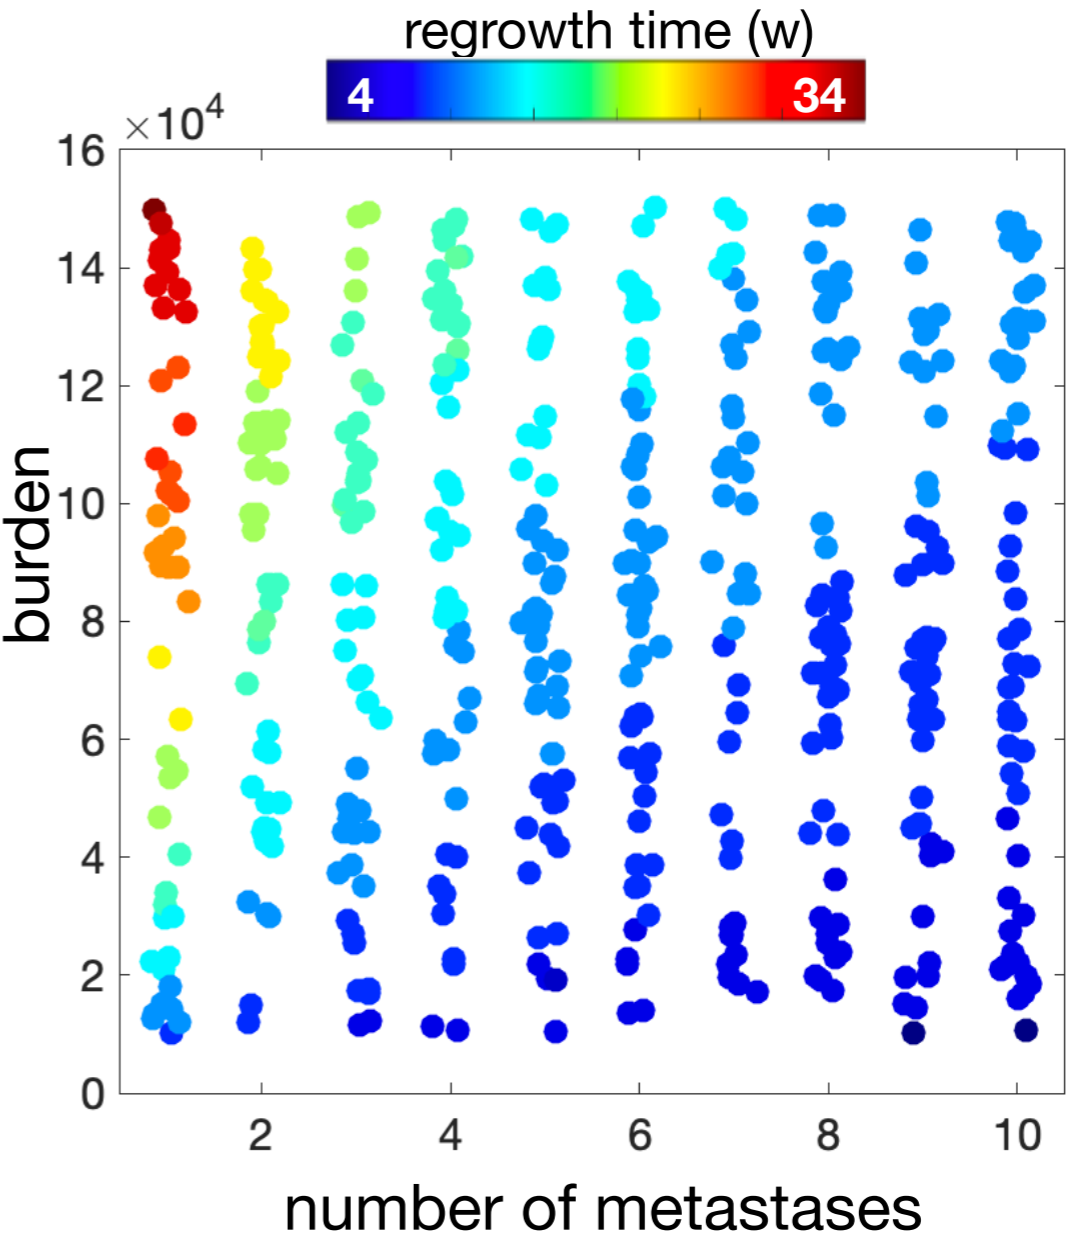

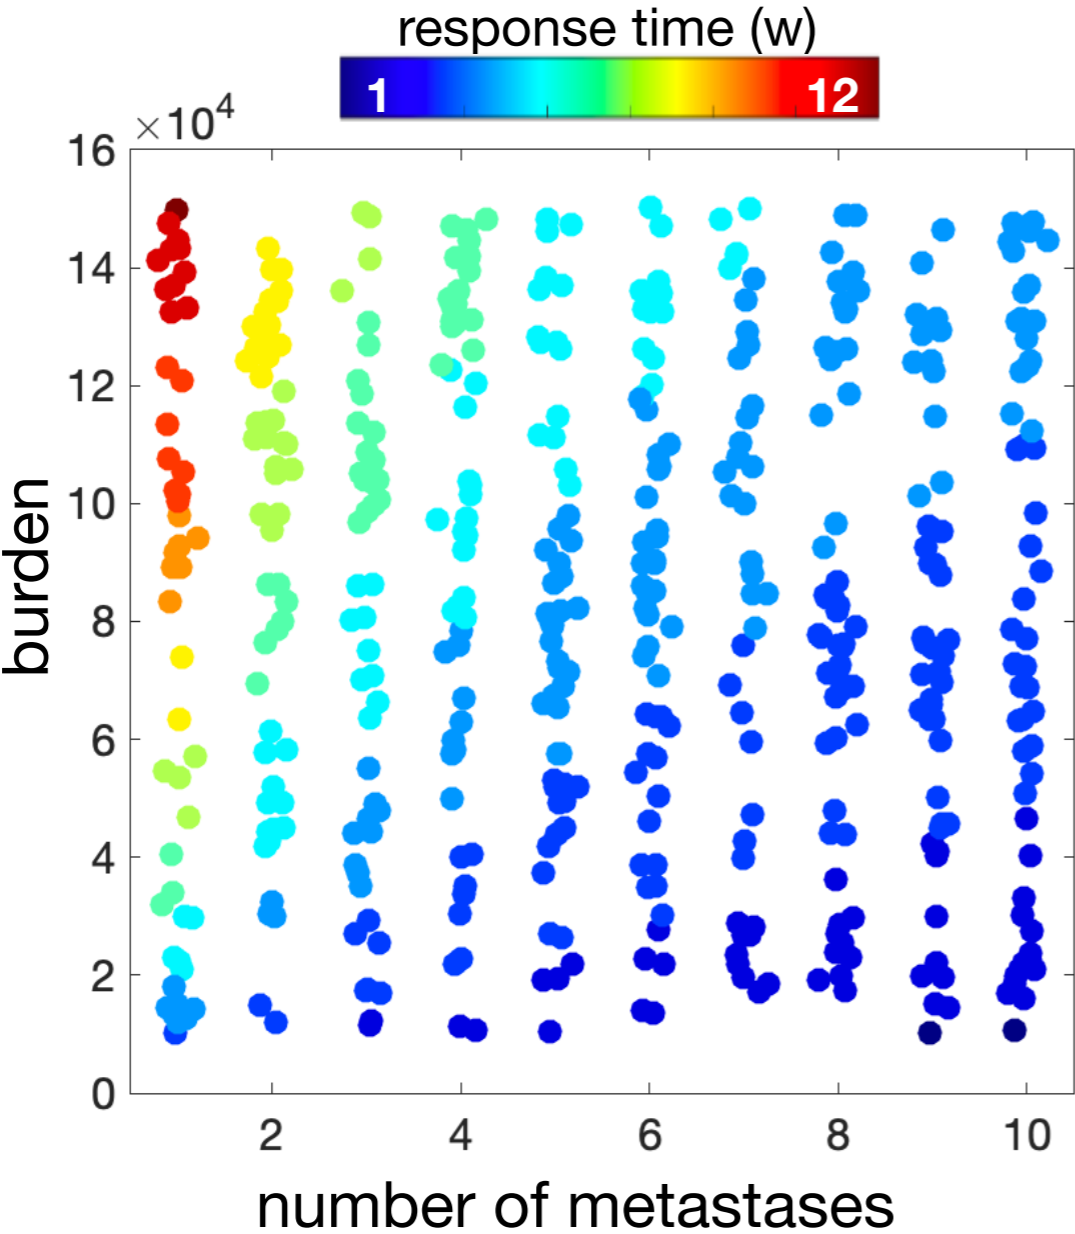

**model:  
cell cycle  
independent  
drug**

How does *burden* and *number of metastases* affect adaptive therapy cycling?

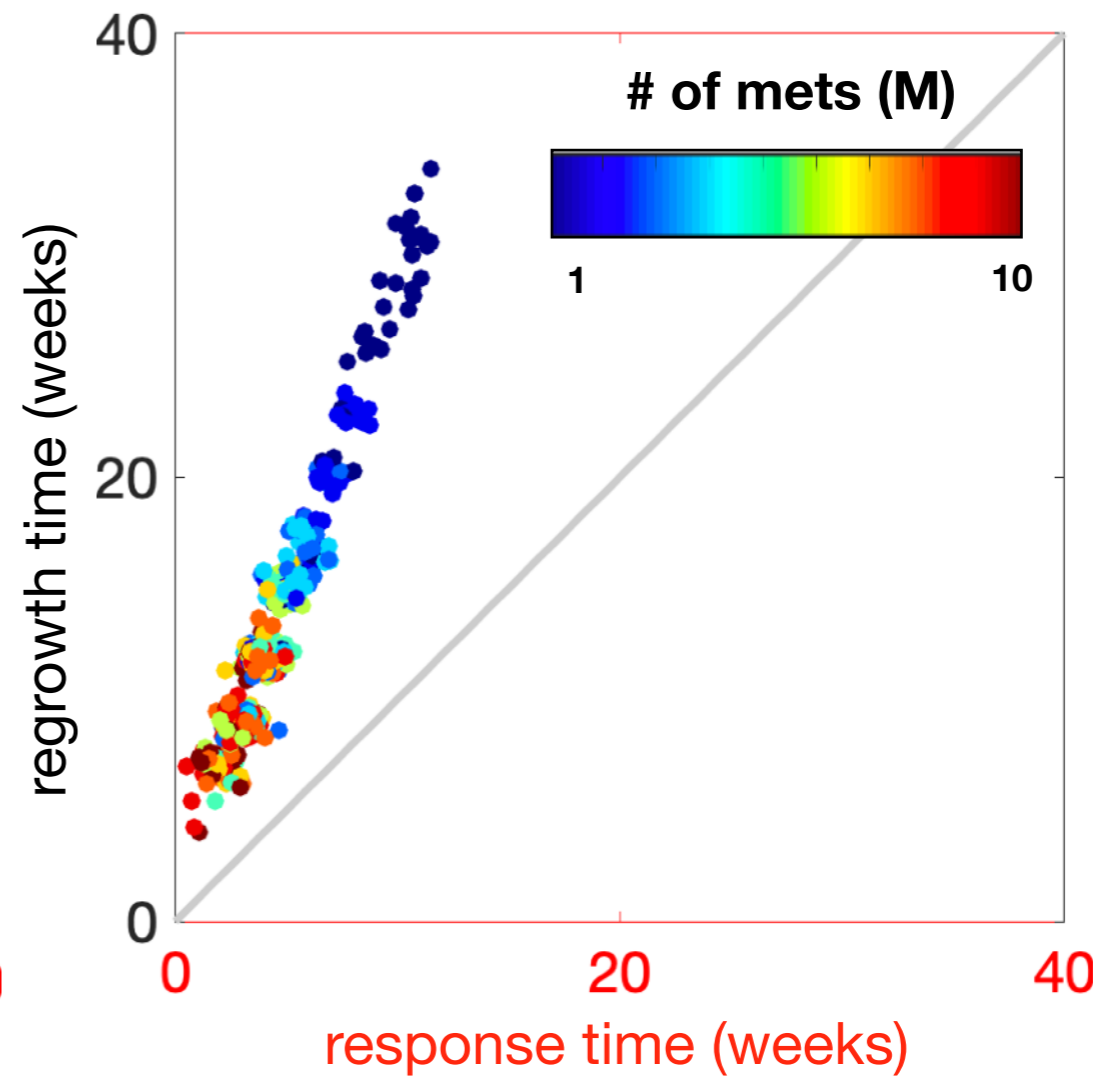

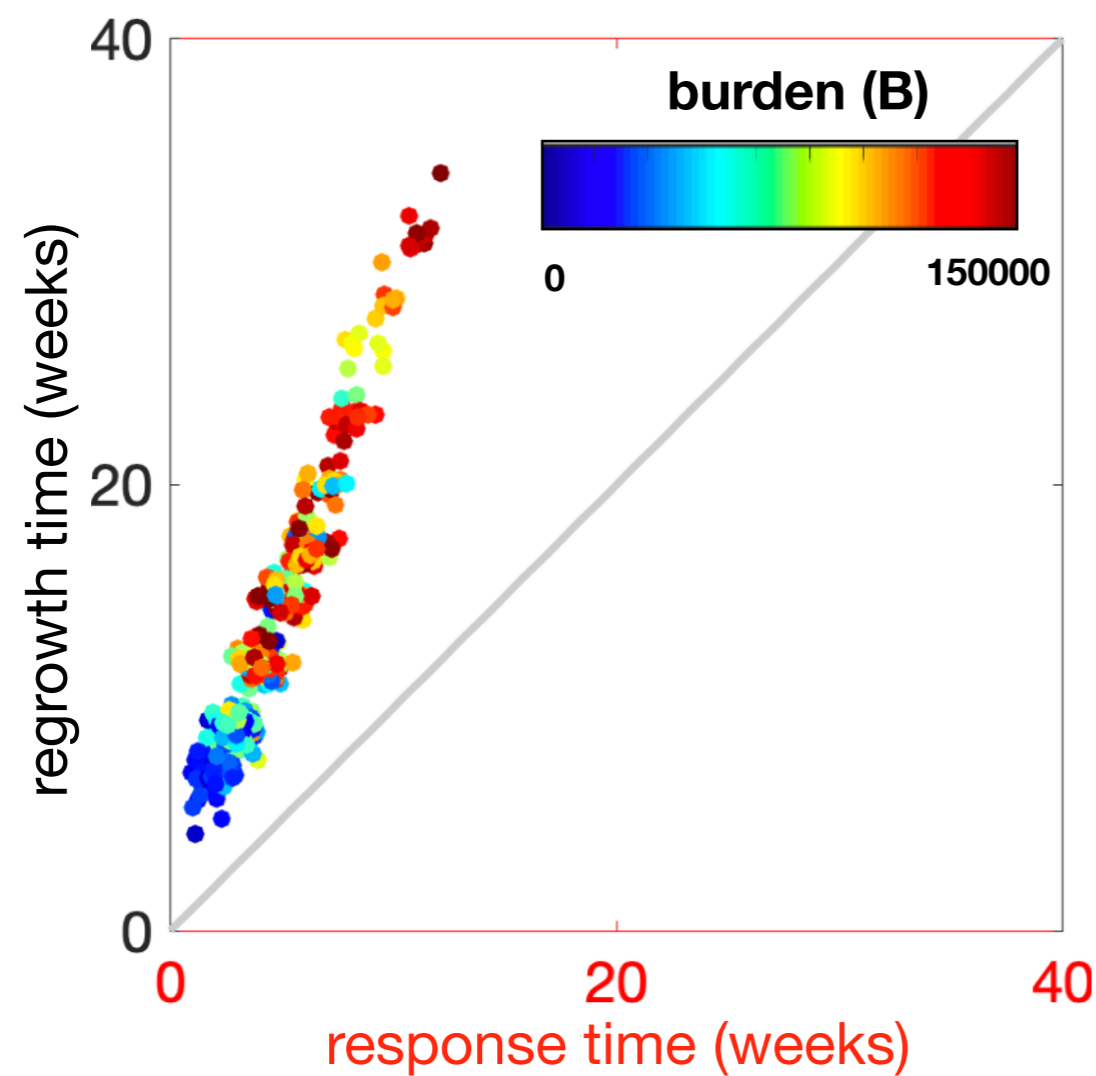

Longer cycles for few mets with high burden  
Shorter cycles for many mets with low burden

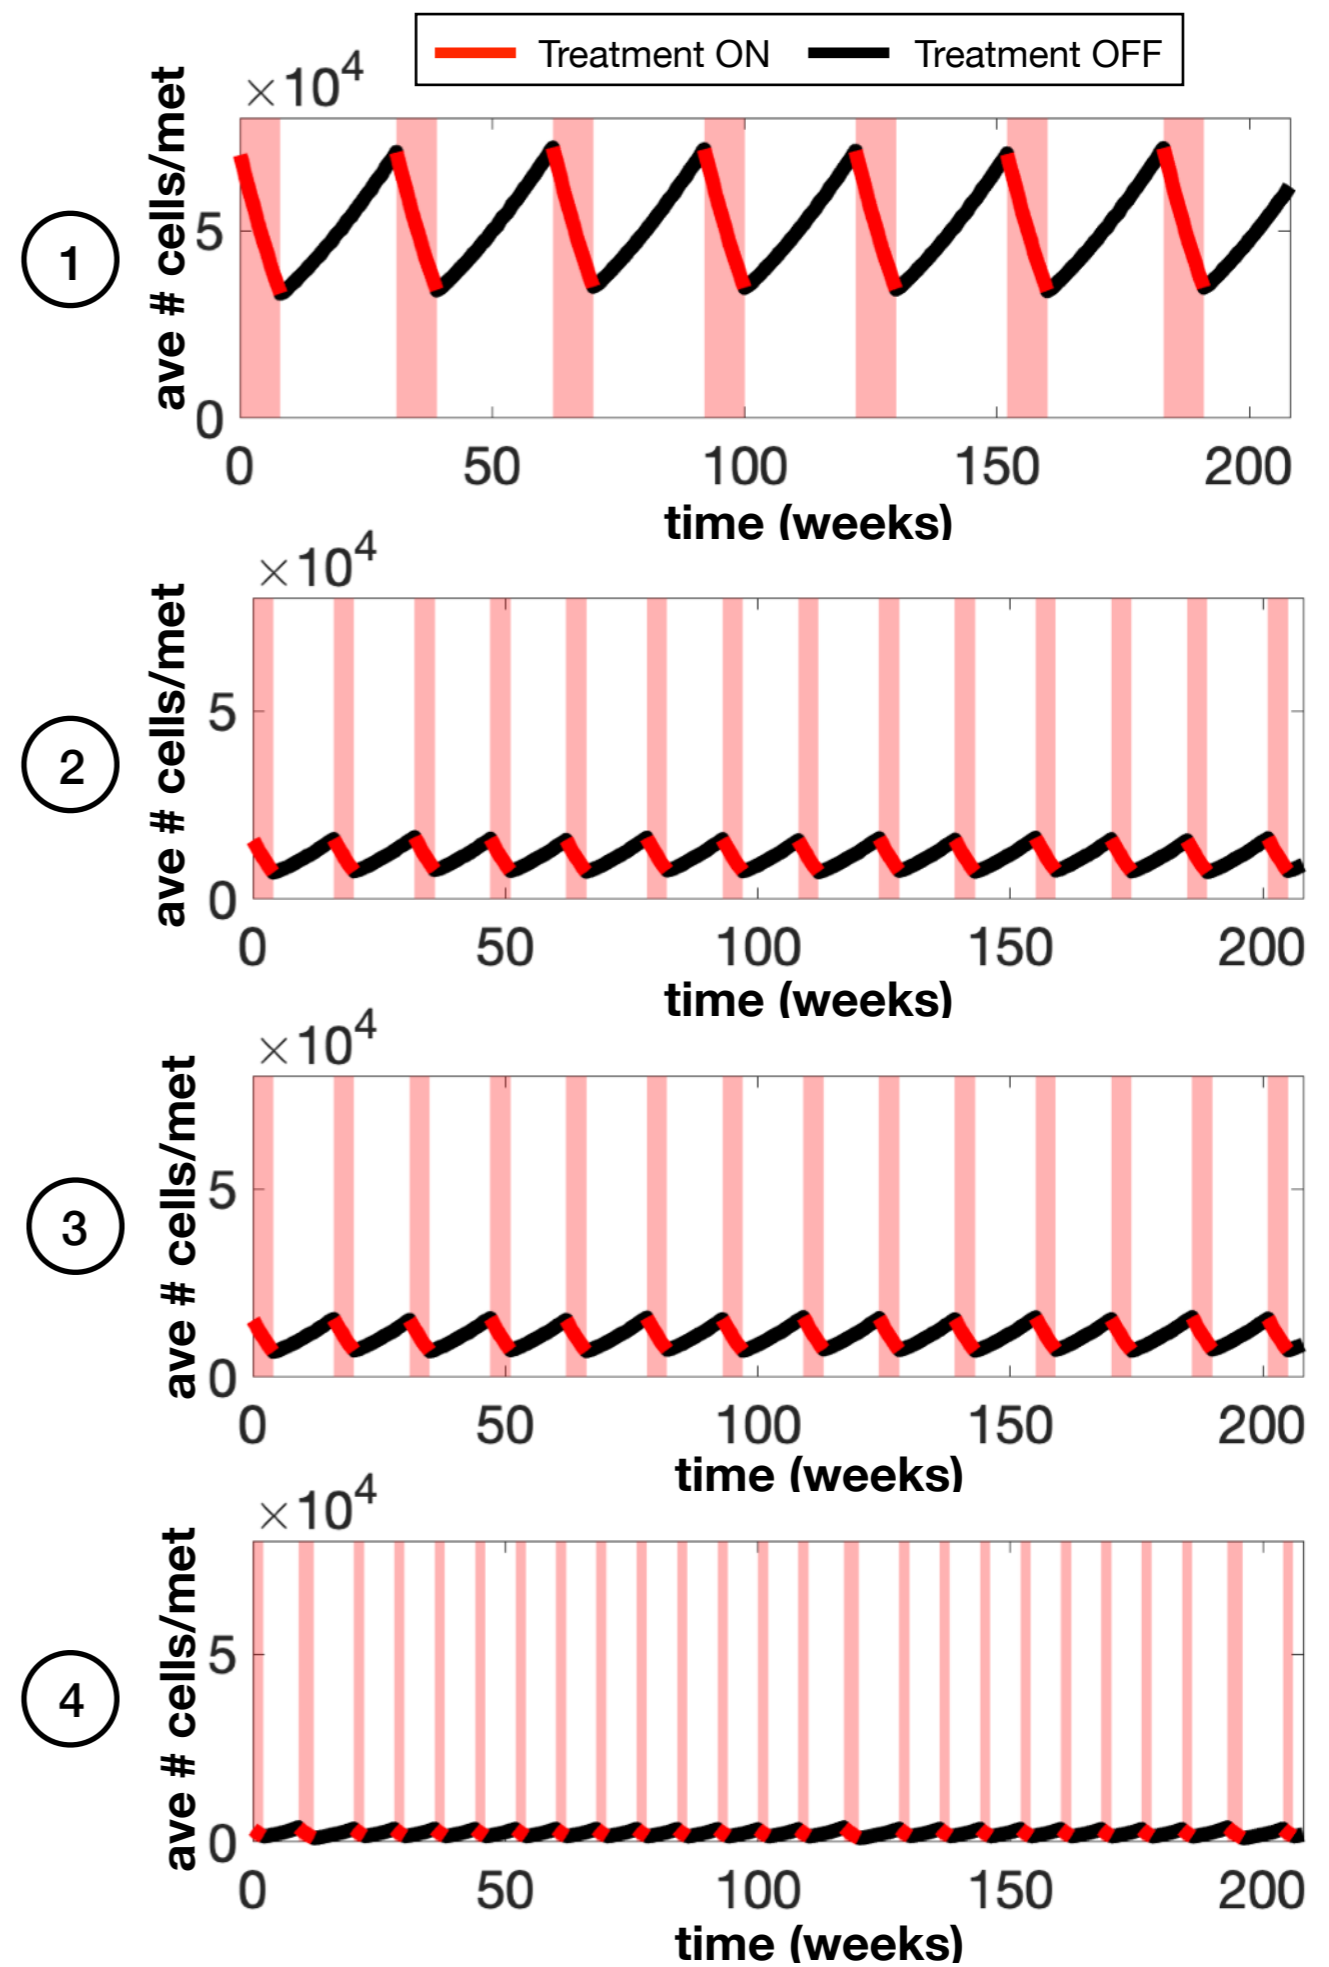

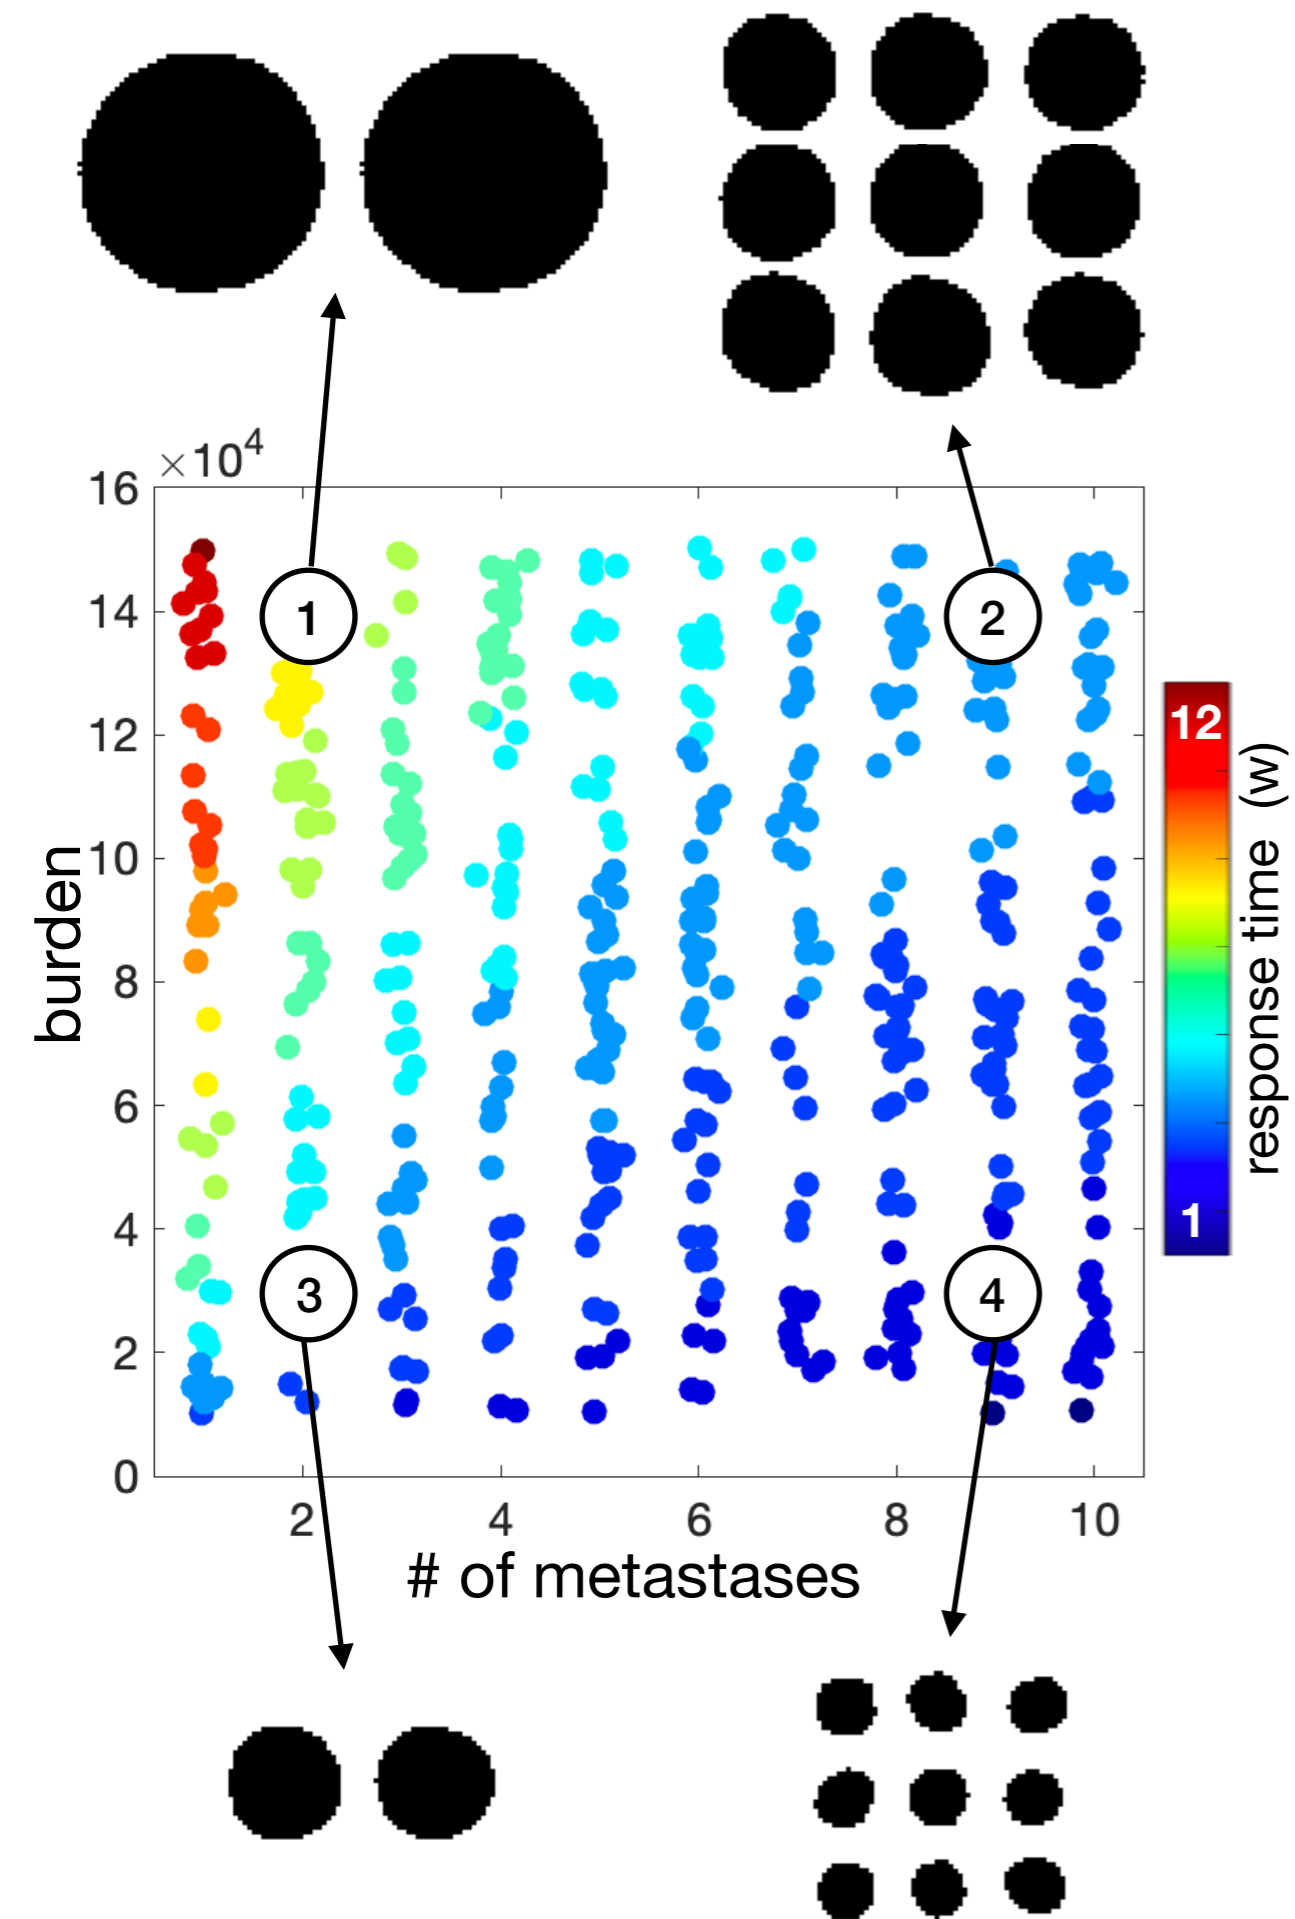

Parameter	Value
b	20,000-150,000
m	1-10
s	100
d	0
$\sigma_{S1}$	0
$\sigma_{S2}$	0

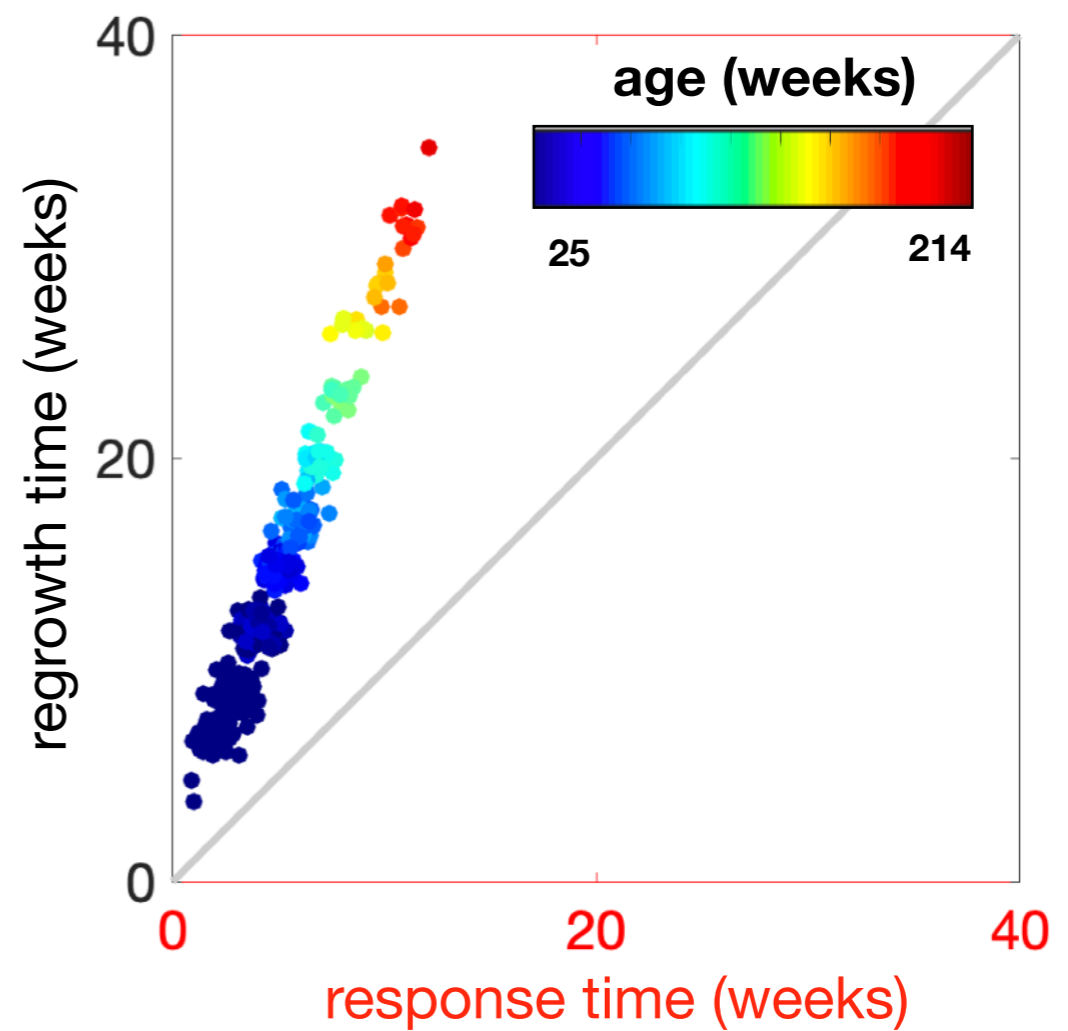

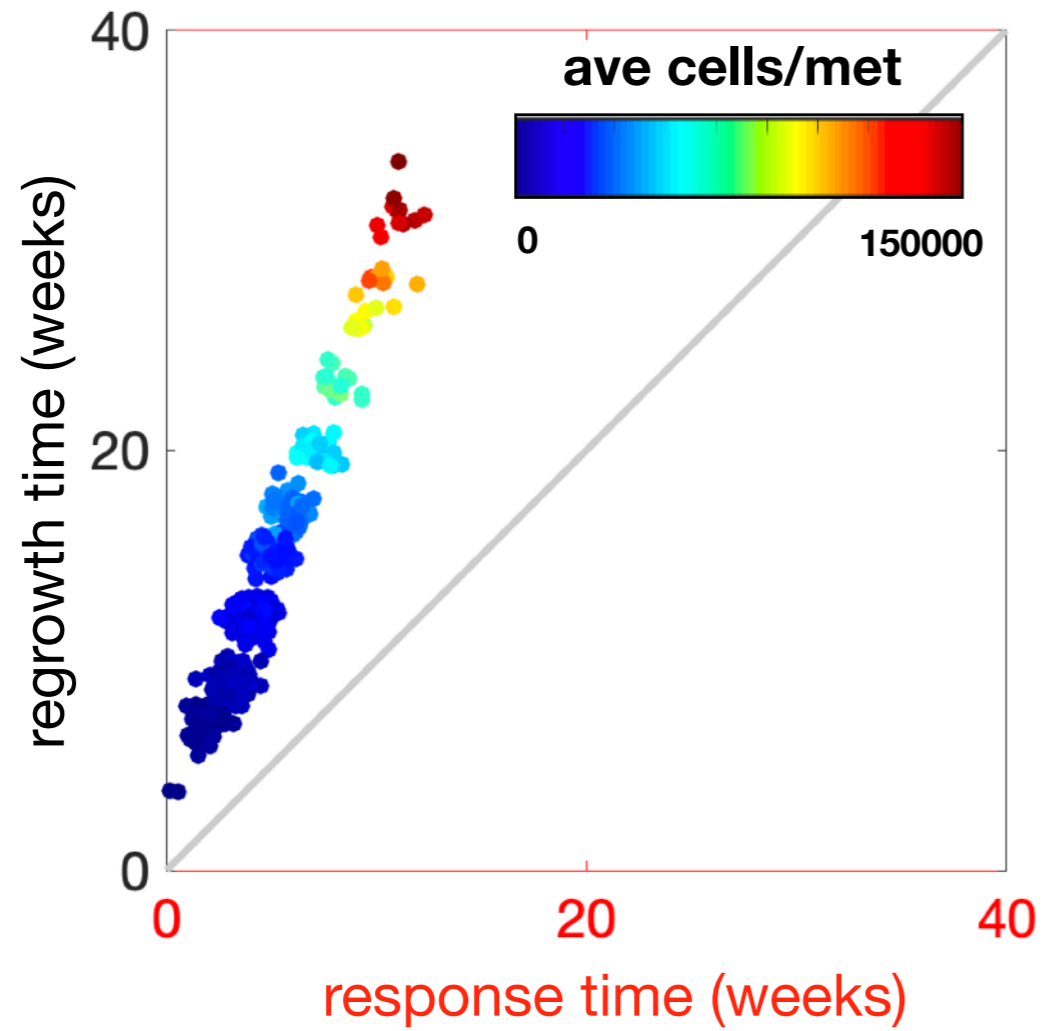

## Some correlation with

1. Shorter cycles: small burden and many mets
2. Longer cycles: higher burden and few mets

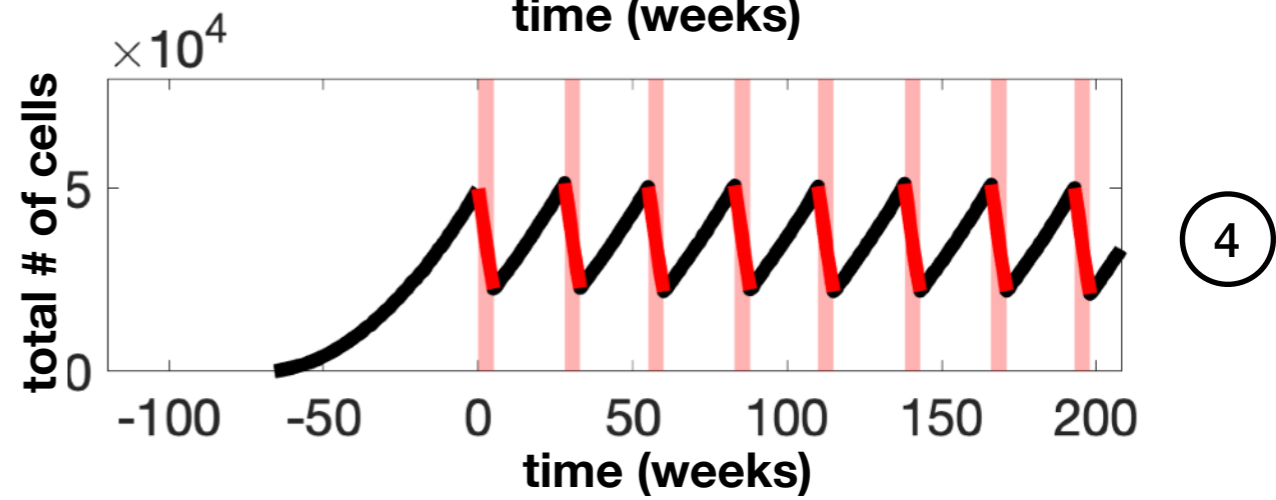

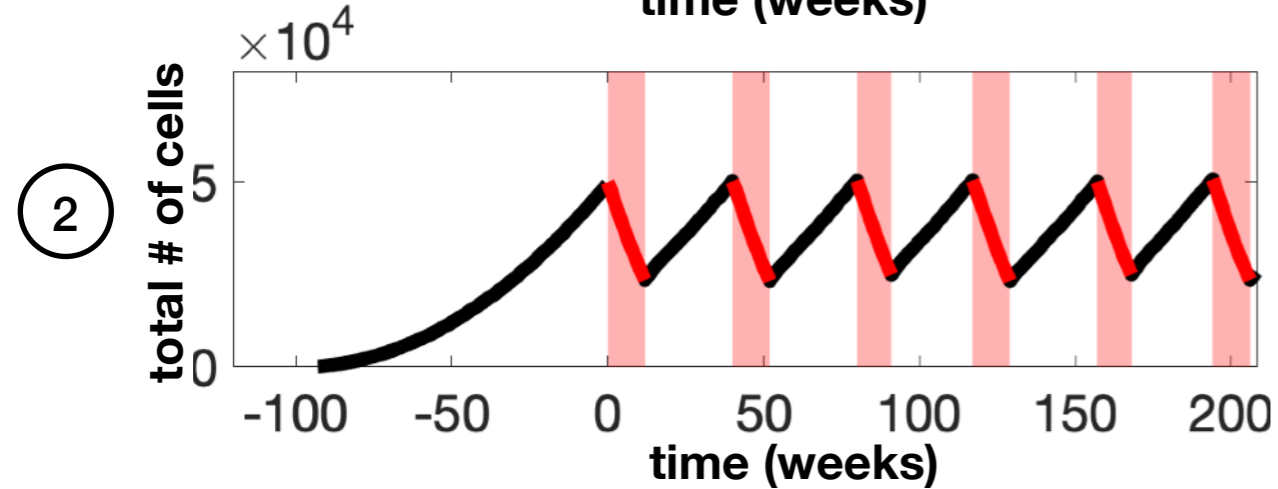

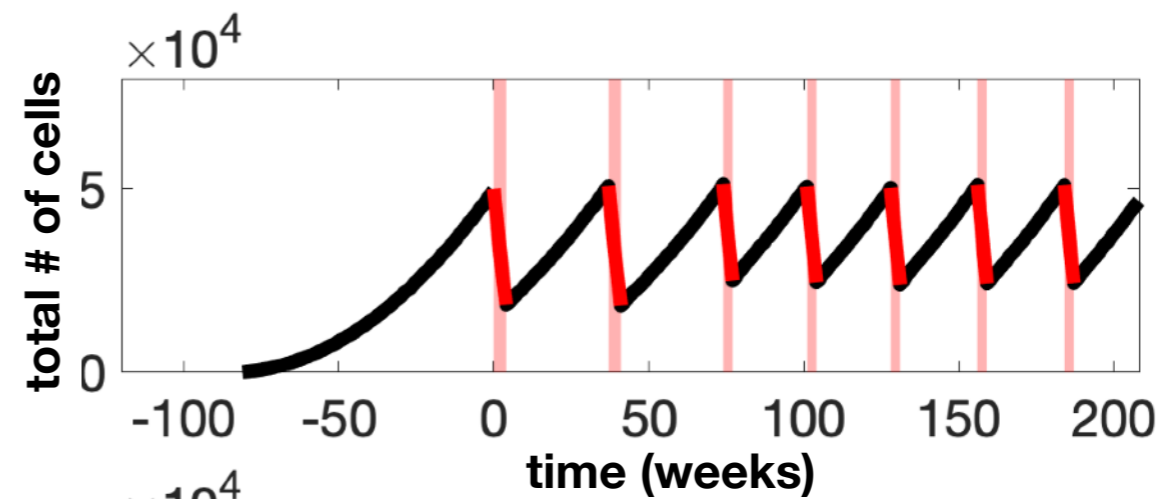

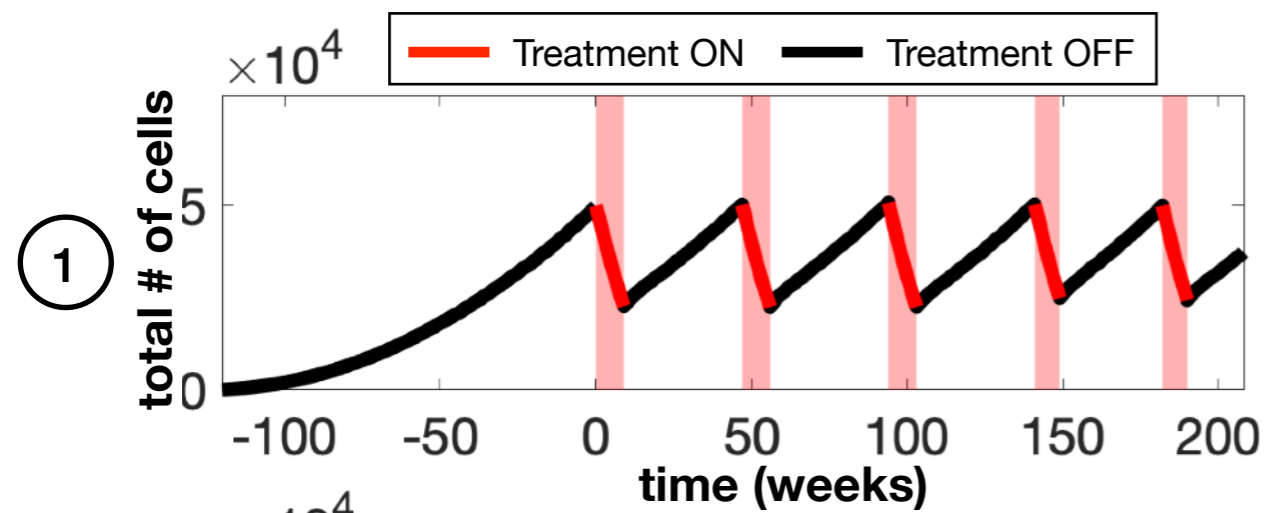

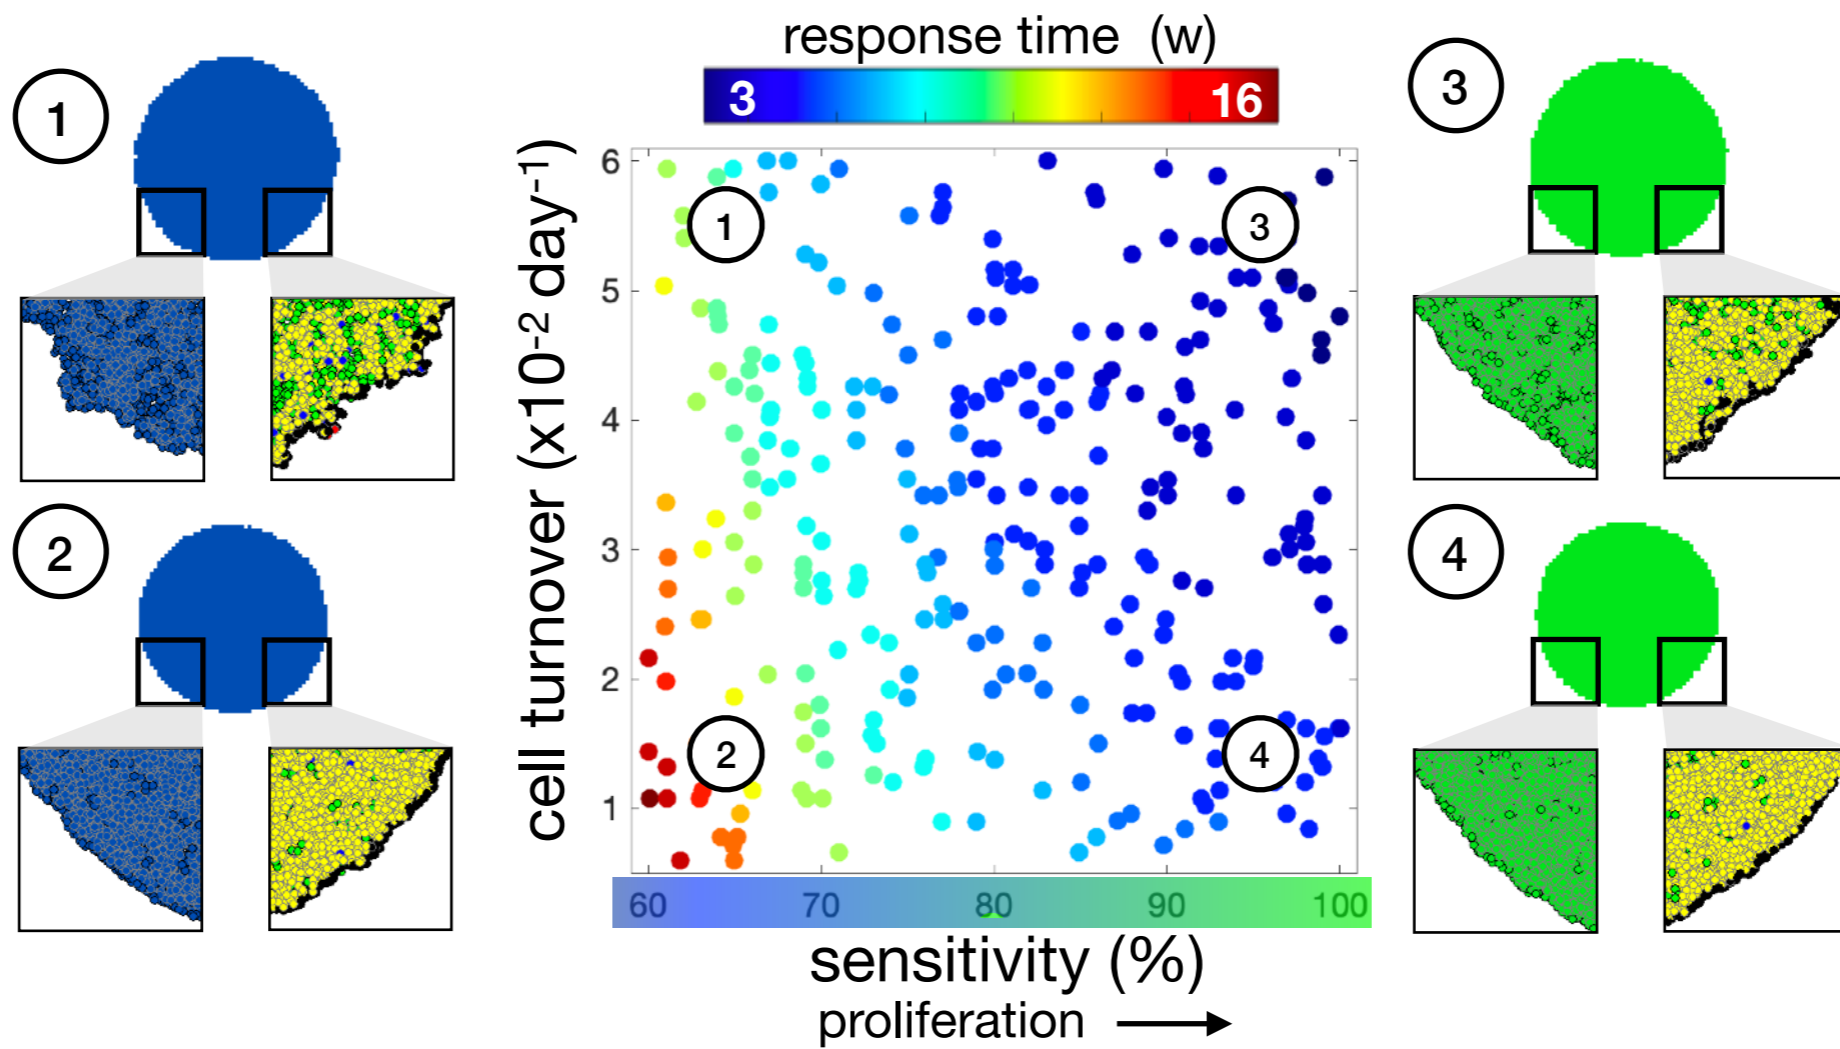

**Shorter cycles: younger and smaller**  
**Longer cycles: older and larger**

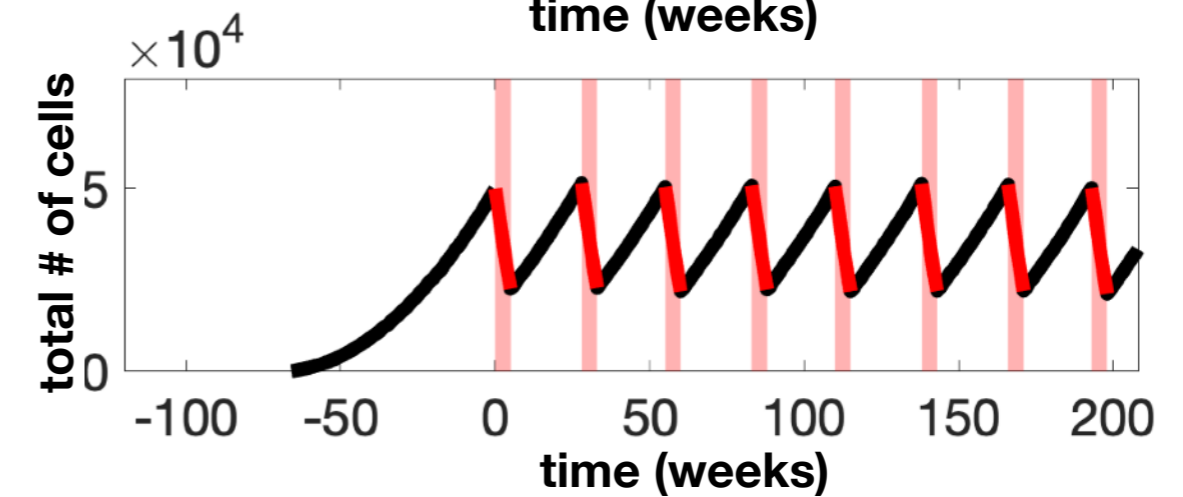

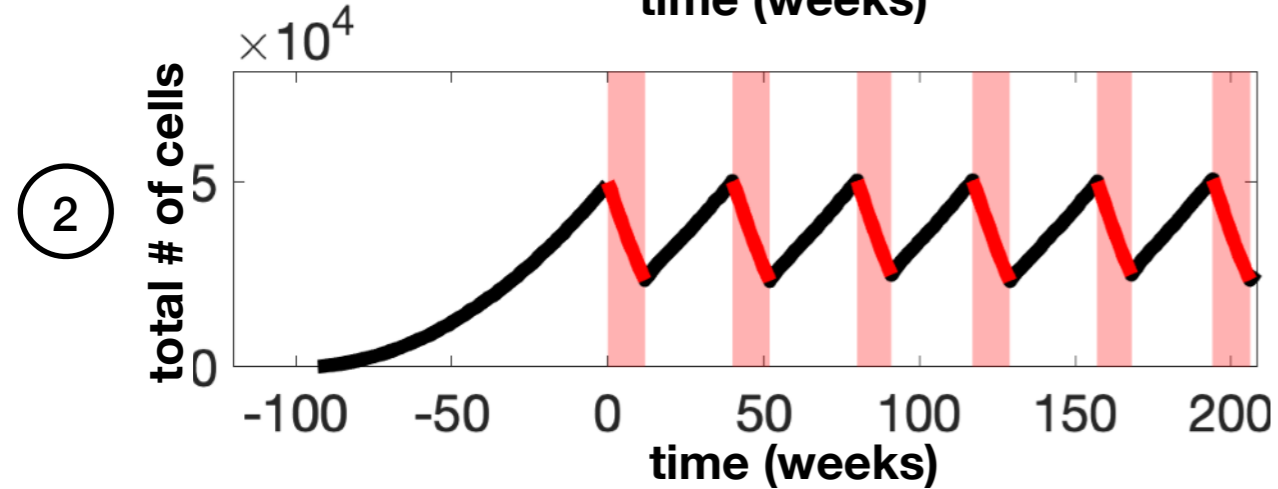

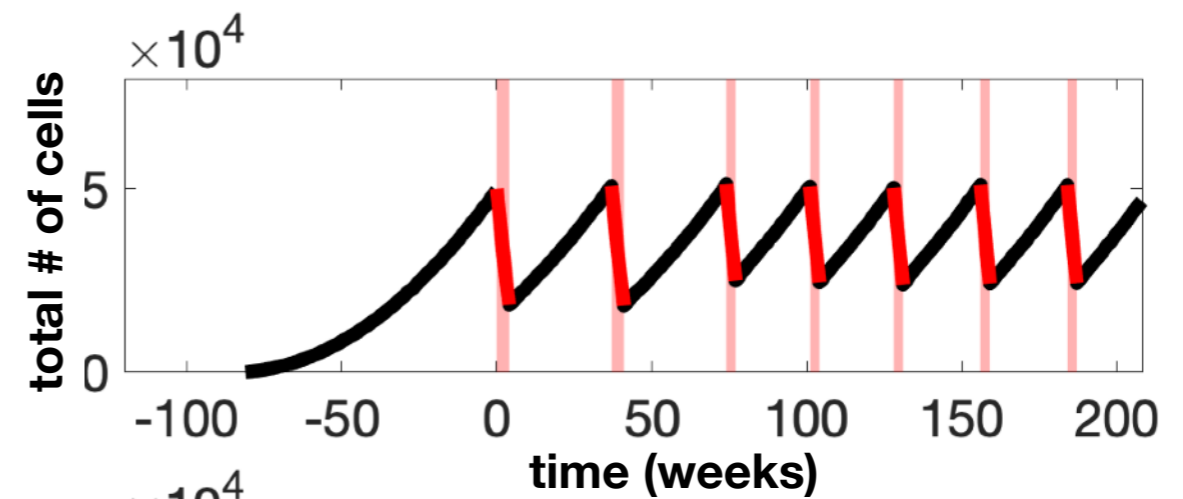

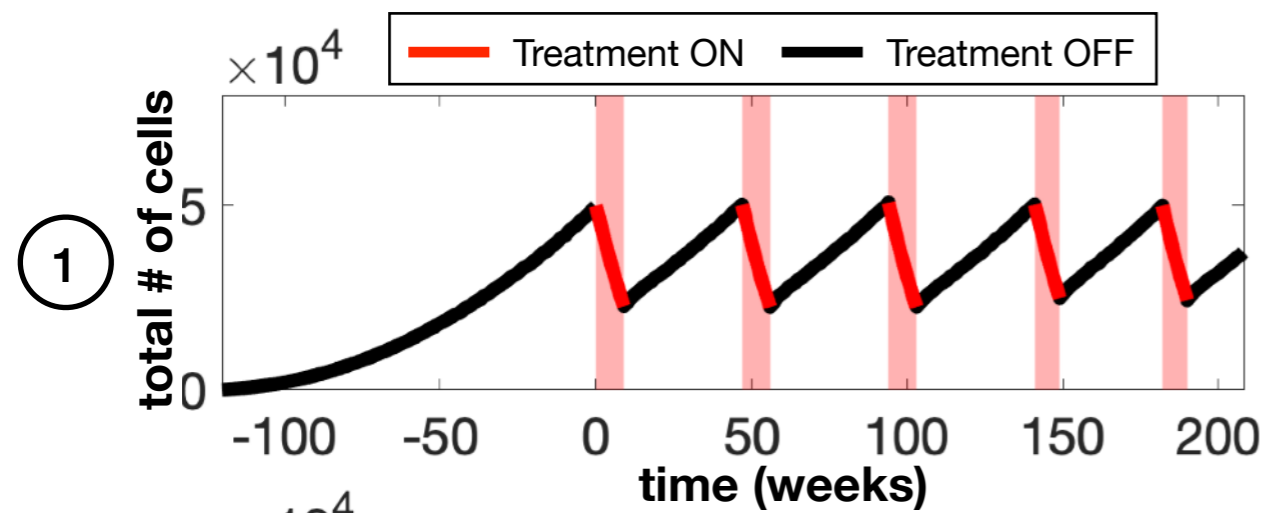

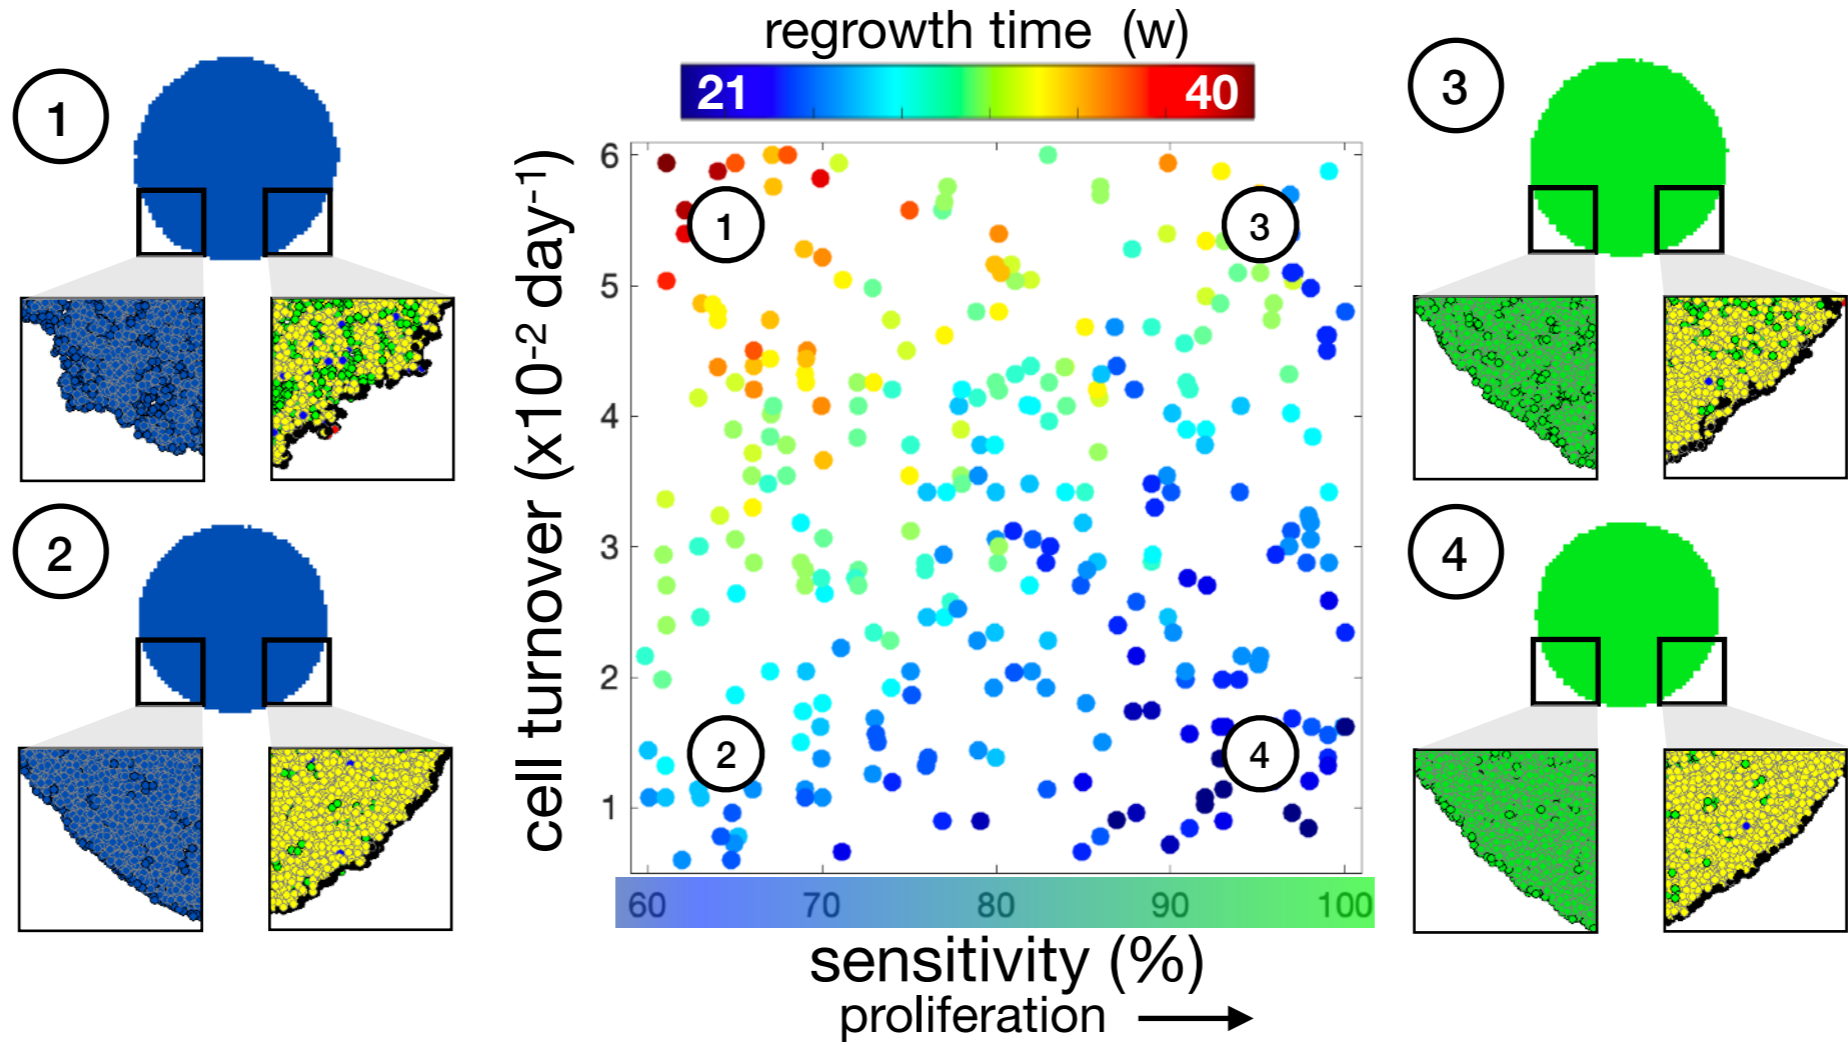

## How does *sensitivity* and *cell turnover* affect adaptive therapy cycling?

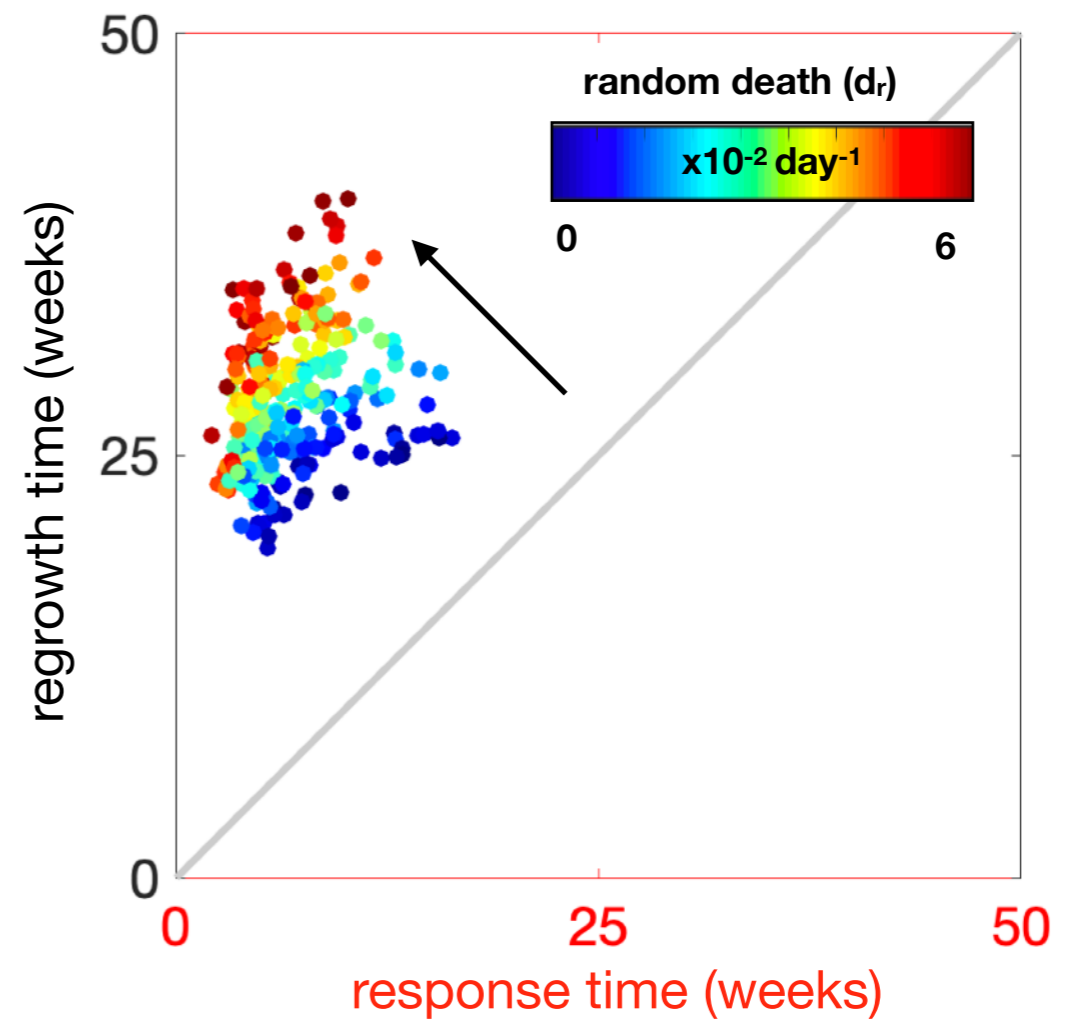

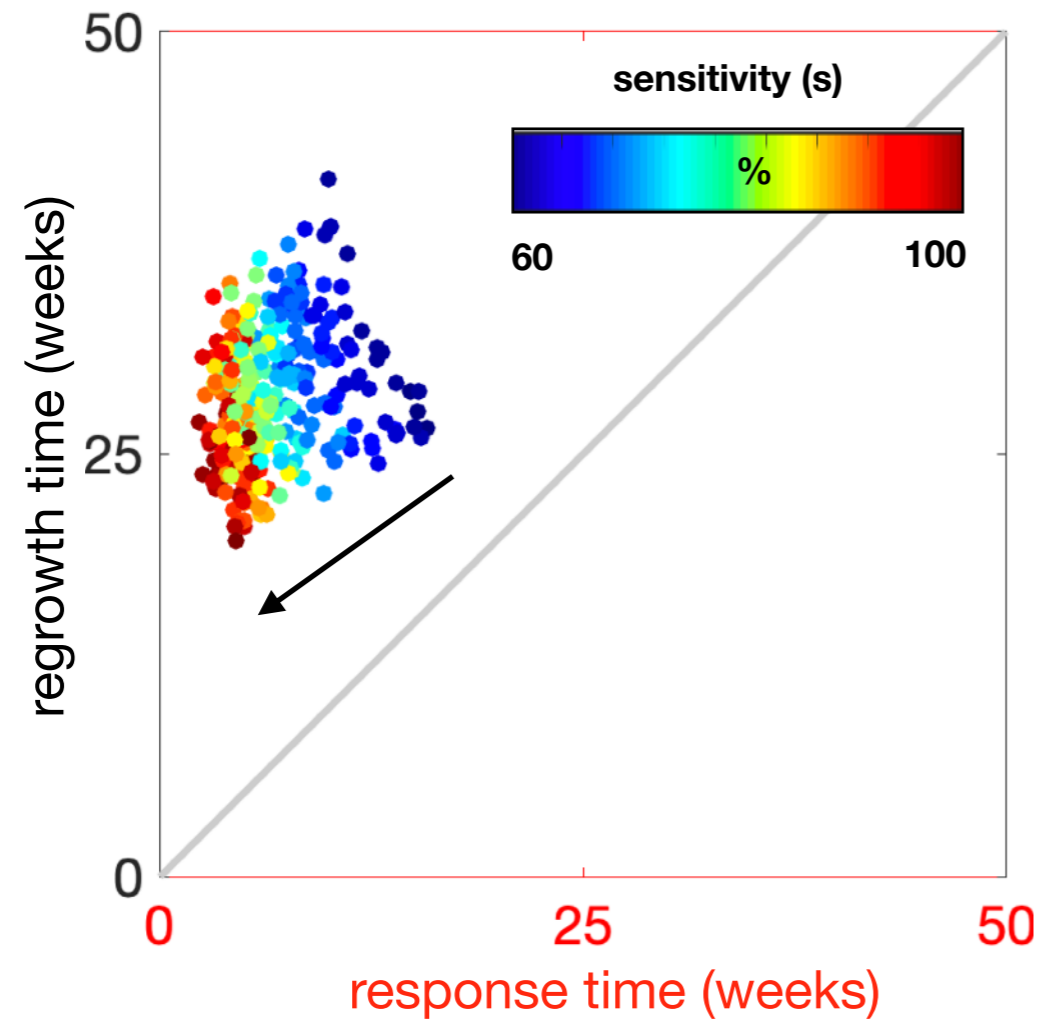

Parameter	Value
b	50,000
m	1
s	60-100
d	0-0.06
$\sigma_{S1}$	0
$\sigma_{S2}$	0

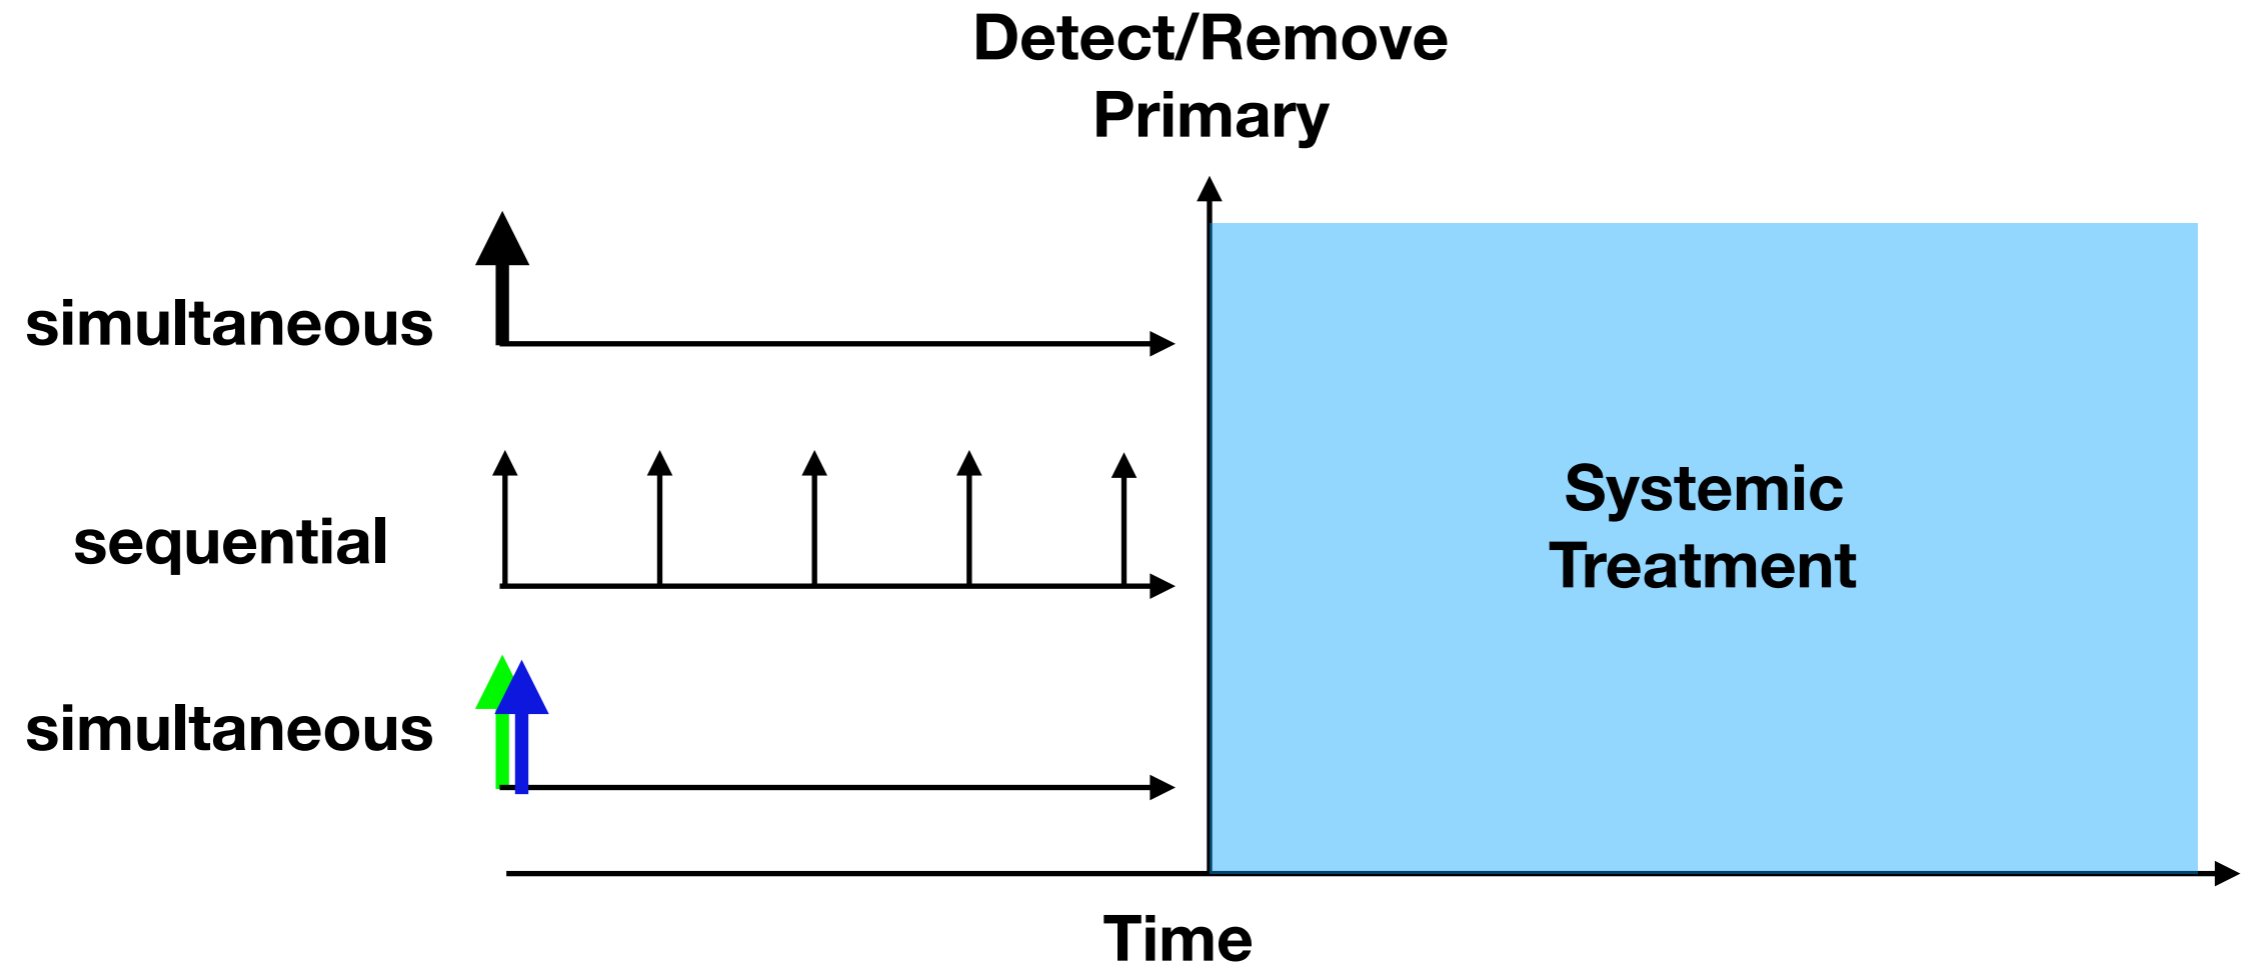

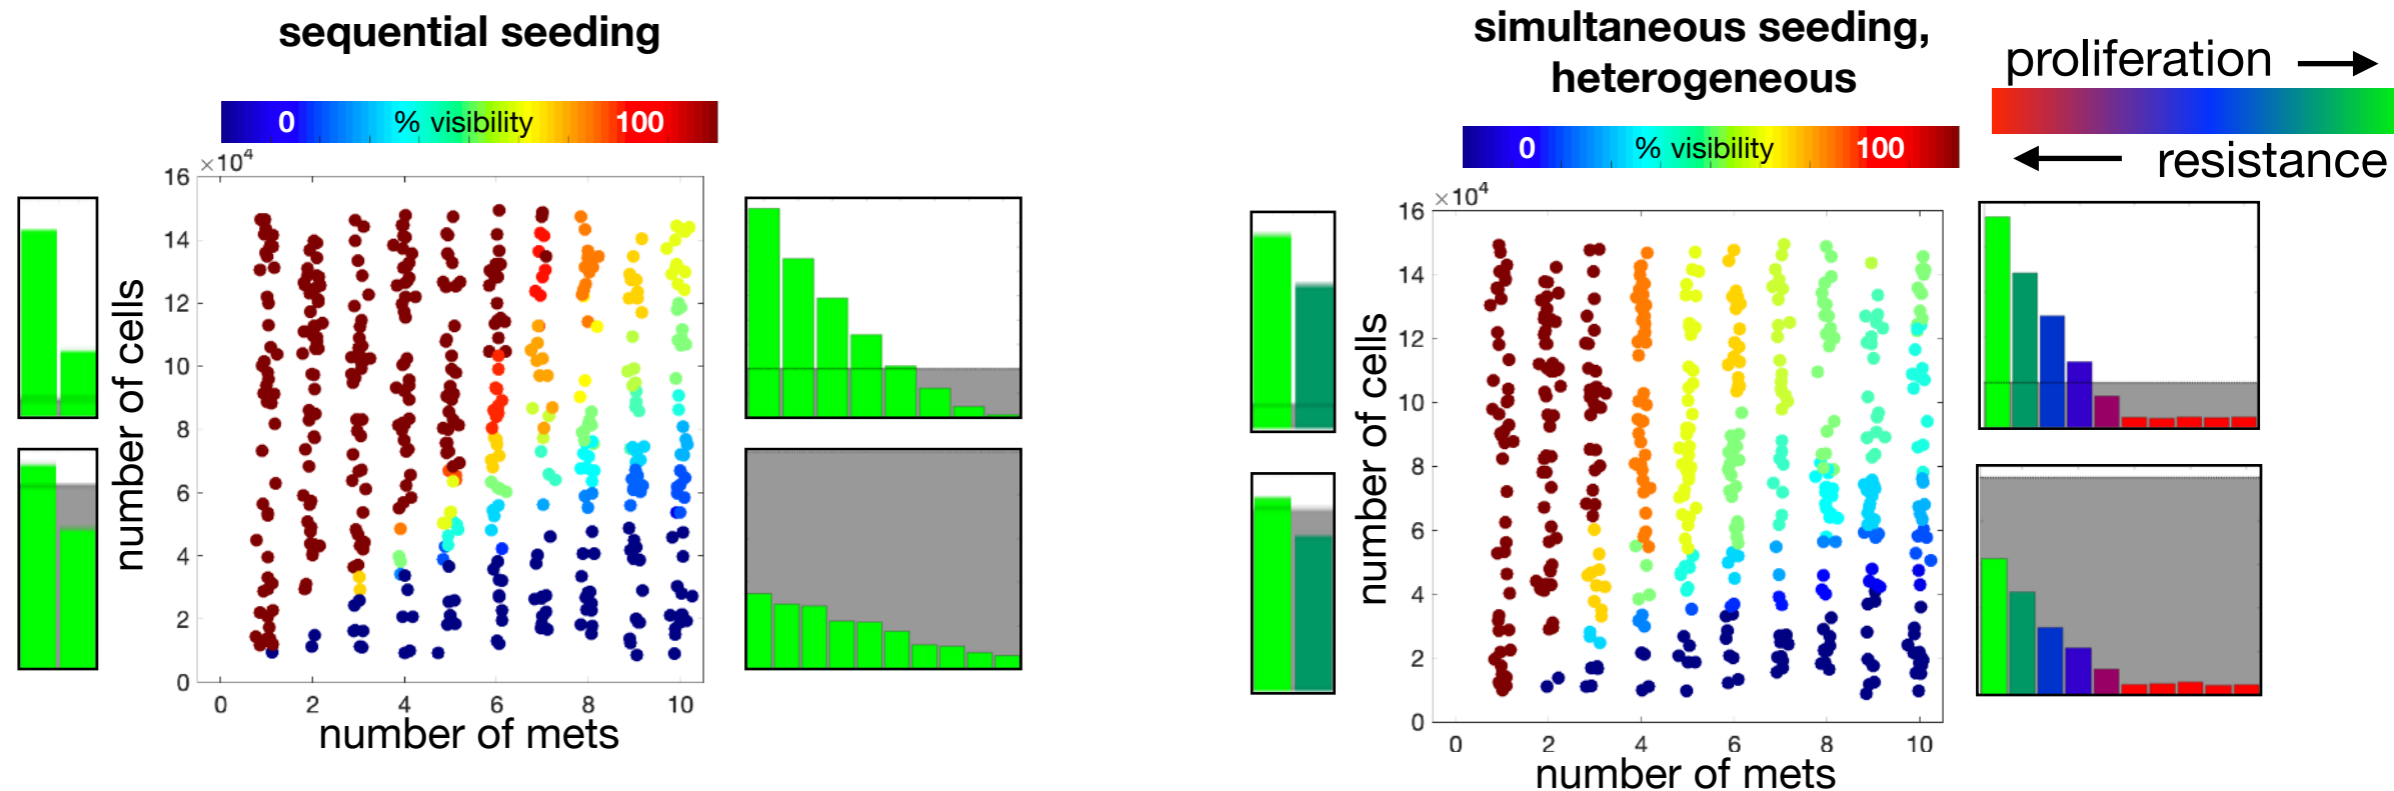

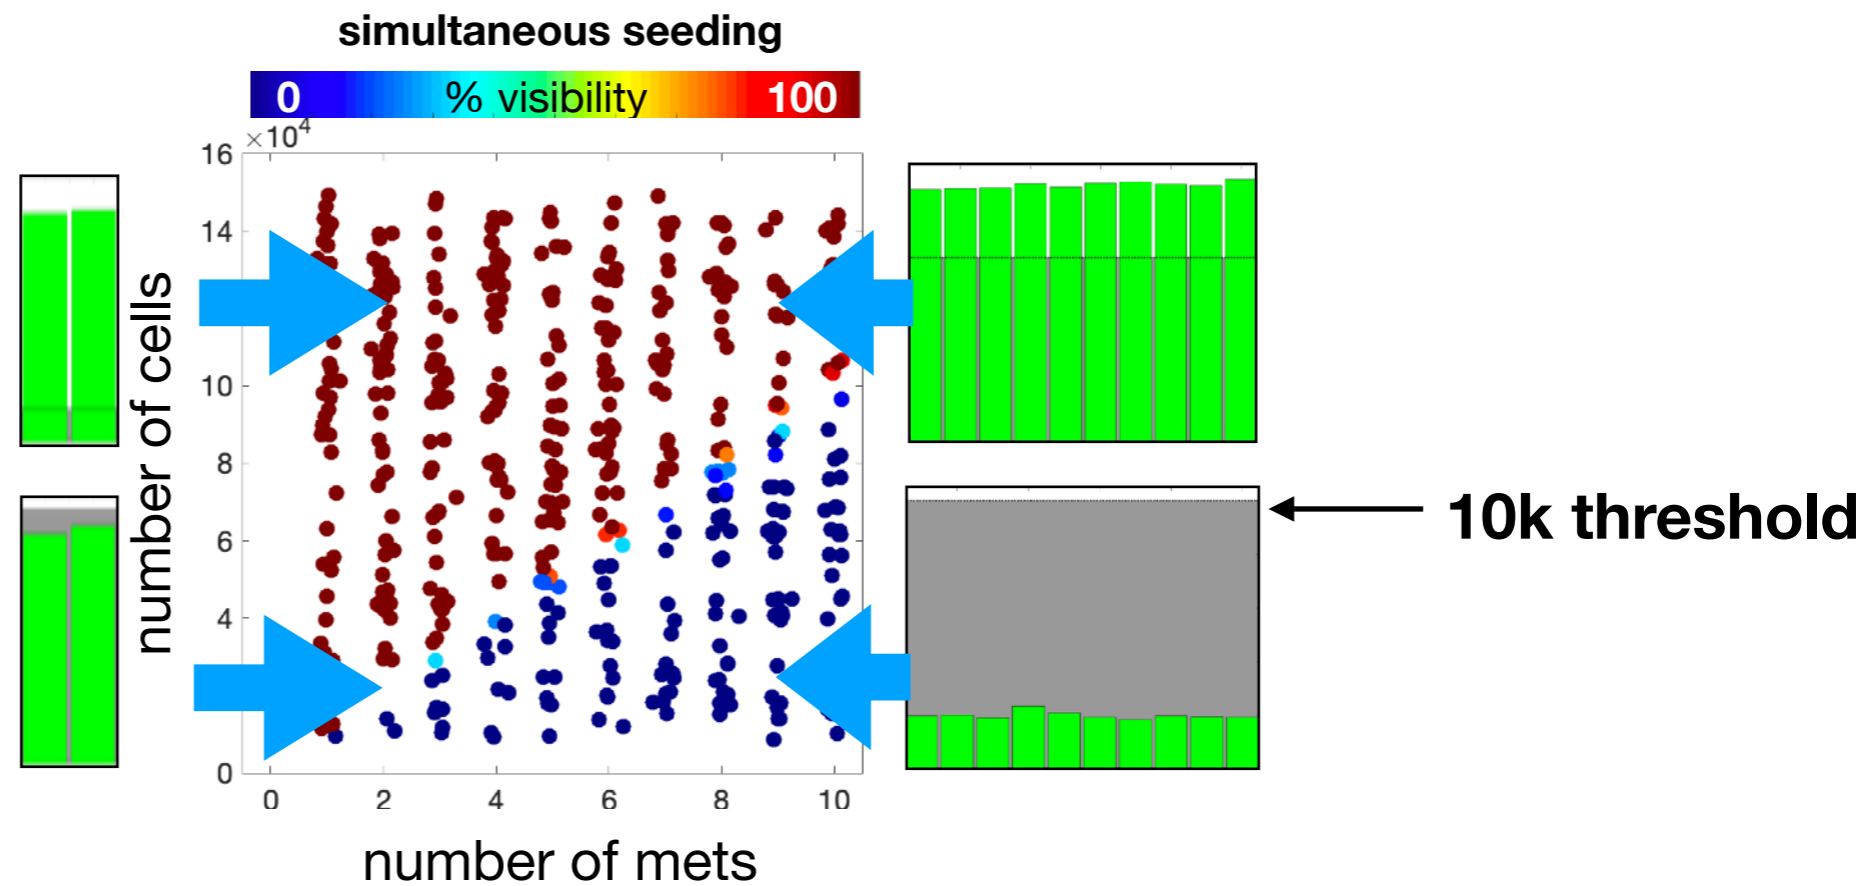

**More sensitive: quicker response/regrowth times**  
**More turnover: quicker response times, longer regrowth times**

# How does seeding/heterogeneity affect observed burden?

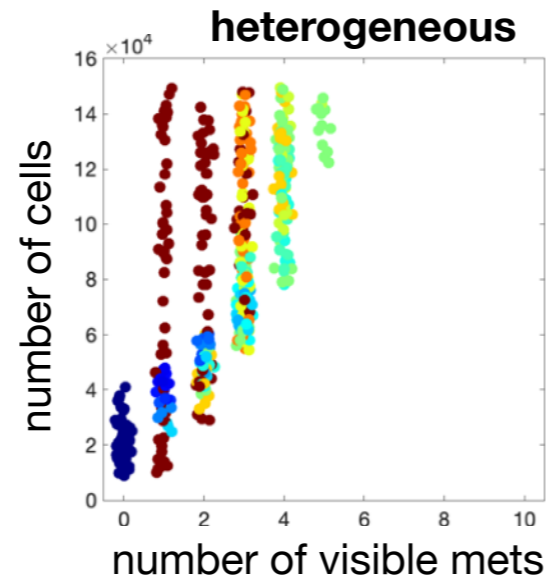

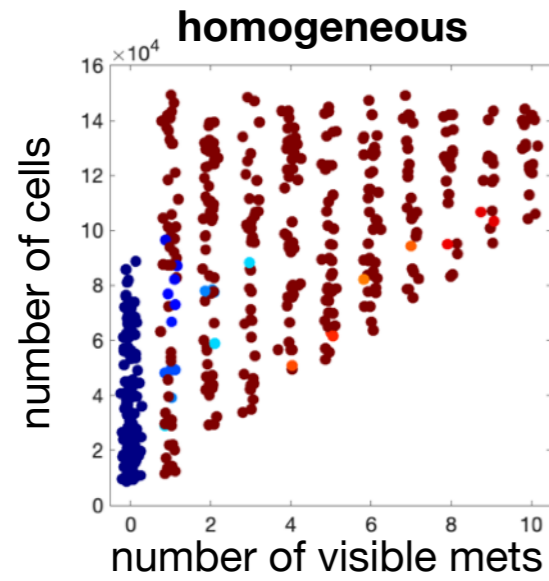

# Metastases below the threshold of visibility

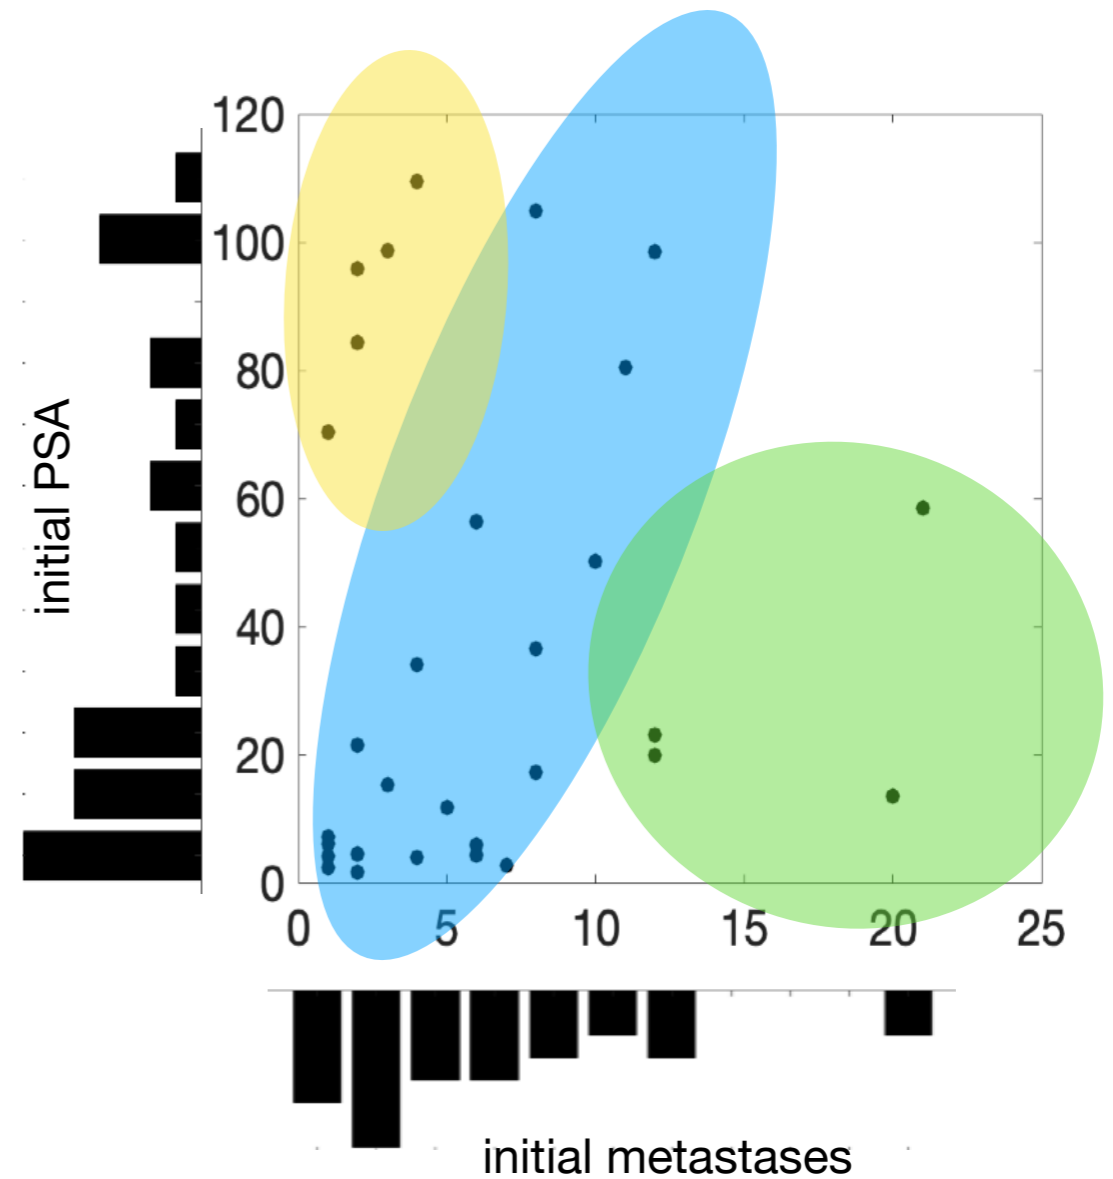

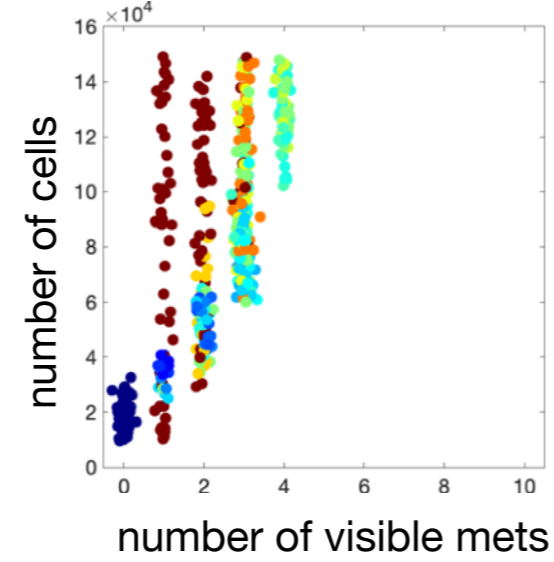

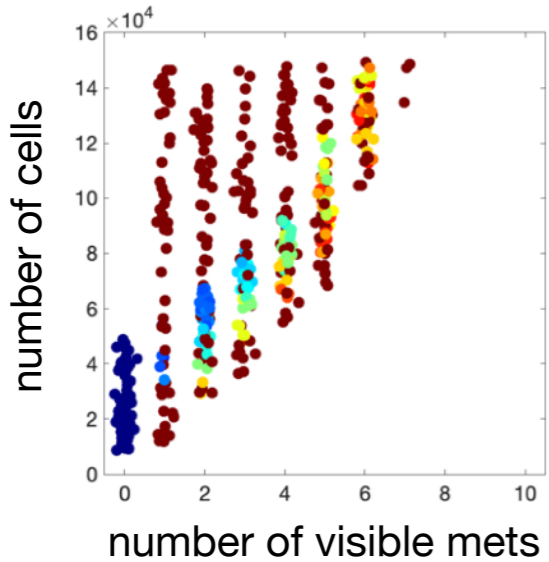

# Many mets with low burden could go undetected

0 % visibility 100

simultaneous seeding

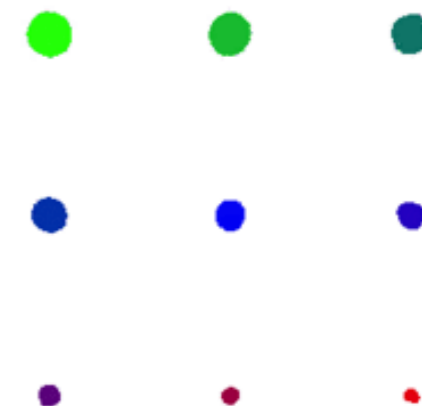

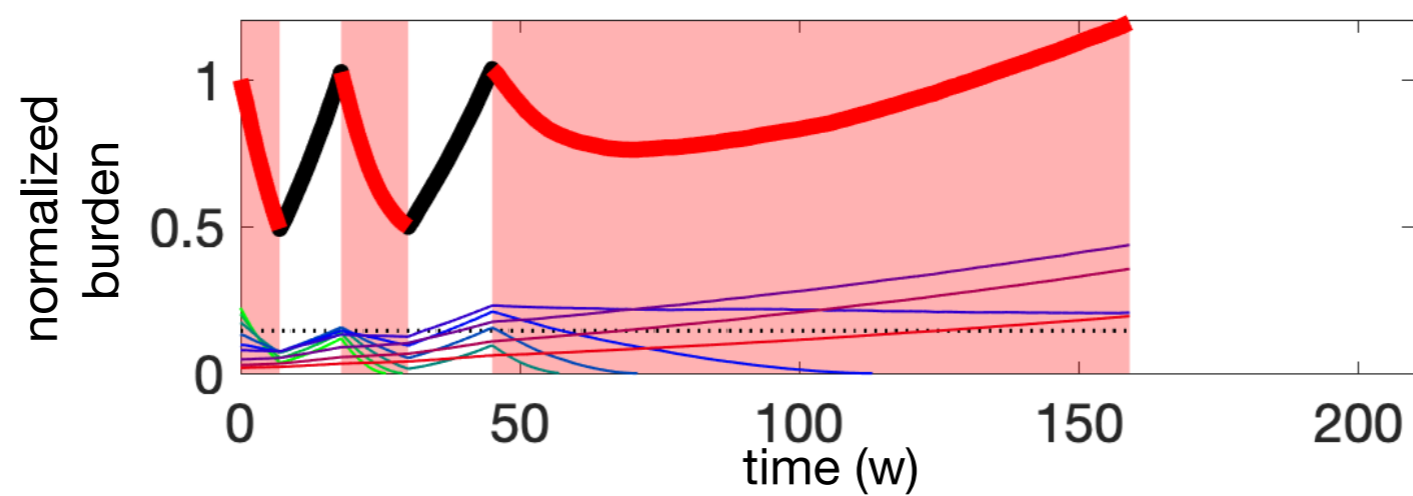

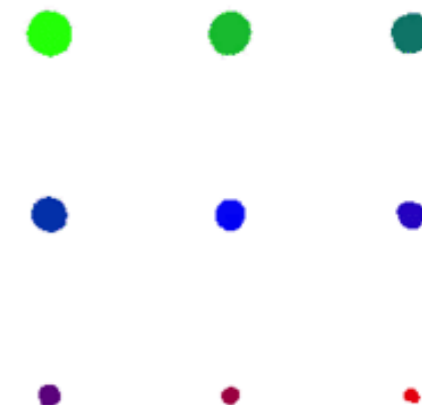

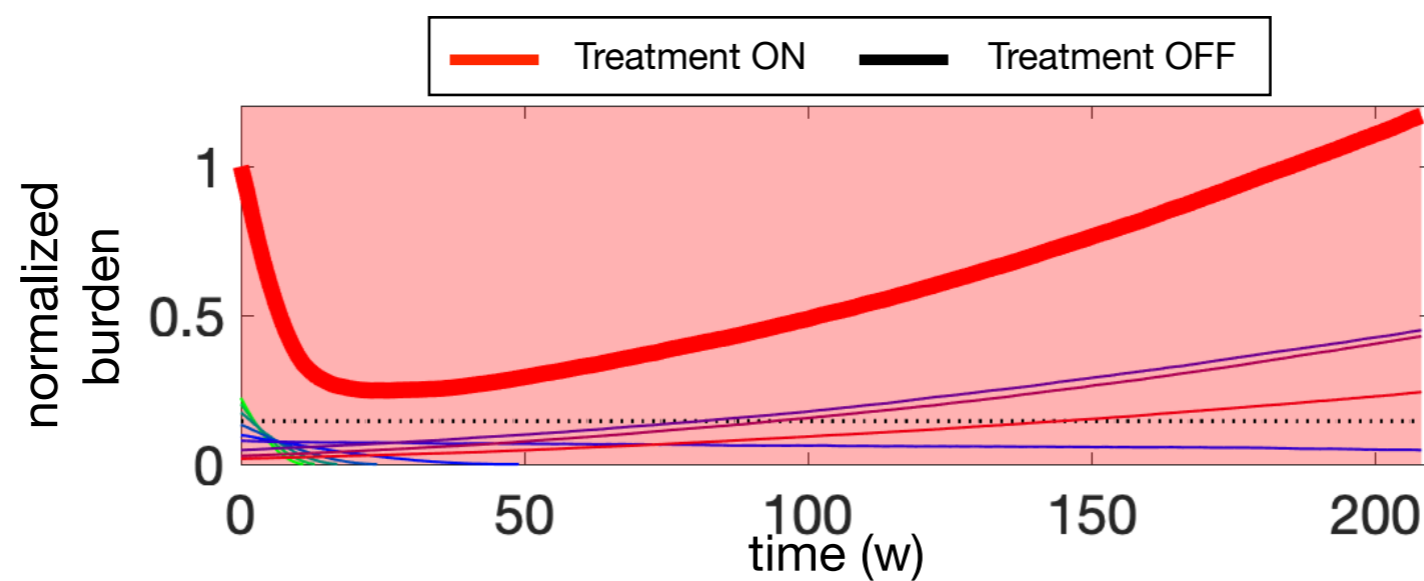

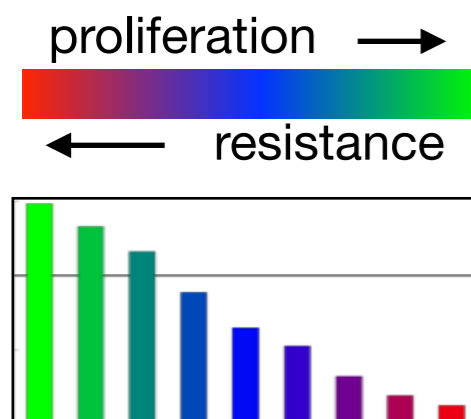

sequential seeding

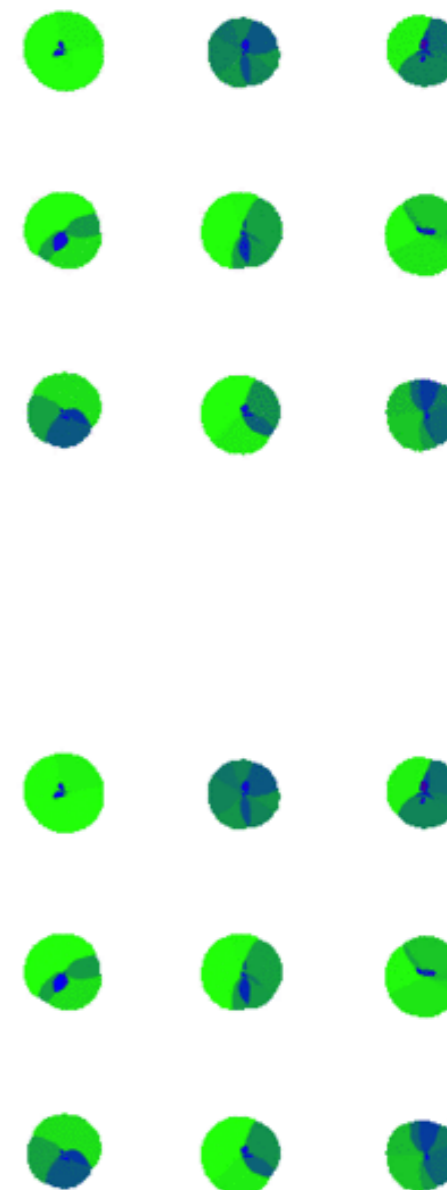

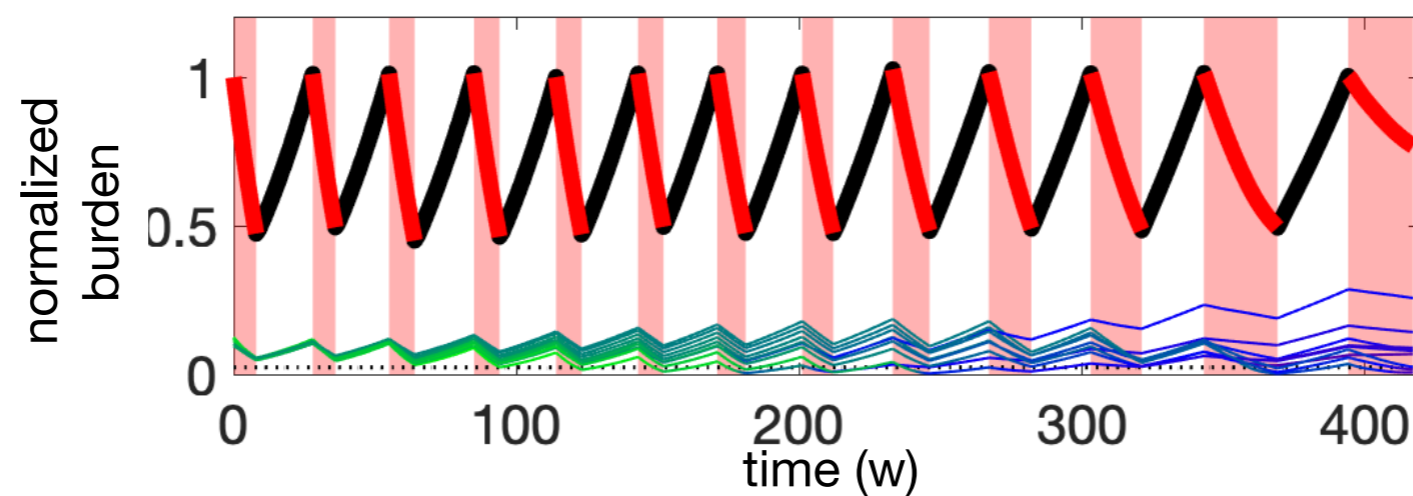

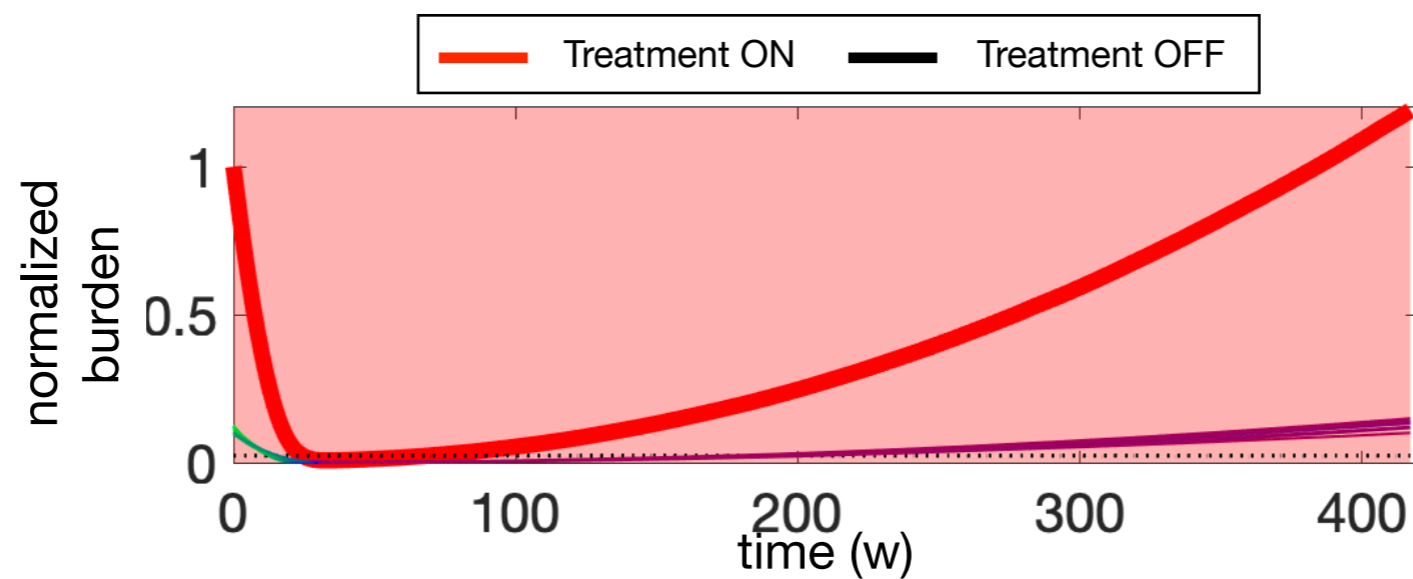

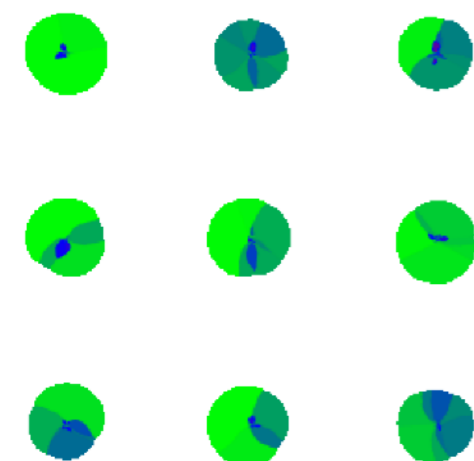

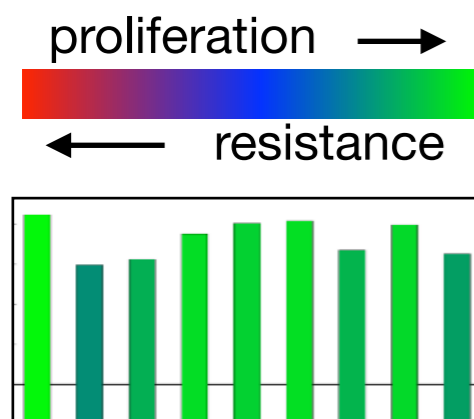

**How does heterogeneity affect longer term  
adaptive therapy dynamics?**

## CT better with intertumor heterogeneity

## AT better with intratumor heterogeneity

# Conclusions

- 1. A cell cycle independent drug leads to shorter response times than regrowth times.**
- 2. Cycles are semi-correlated with burden and number of mets, but there are clear trends associated with tumor size, age, sensitivity, and cell turnover.**
- 3. Micrometastases smaller than the imaging threshold can go undetected but still contribute to tumor burden.**
- 4. CT works better with intertumor heterogeneity and AT works better with intratumor heterogeneity.**
- 5. Characterizing metastases as only a binary state is inadequate.**
